Welcome and Introduction

Webinar: "Endocrine aspects of RASopathies"

"**RASopathies**" represent one of the most common non-chromosomal diseases affecting development and growth.

A brief introduction will outline their genetic heterogeneity and clinical variability.

We'll then explore the endocrinological aspects of **RASopathies,** focusing on key areas such as - growth, growth therapy, puberty and metabolic profiling – to better understand their impact on patient care and long-term outcomes .

The webinar is designed for all specialists involved in the care of individuals with **RASopathies**, particularly pediatricians, endocrinologists, geneticists and, of course, *patients* and *Families*, whose engagement and collaboration remain at the heart of effective management.

Introduction

Webinar: "Endocrine aspects of RASopathies"

Chaired by

- ***Laura Mazzanti***, - Alma Mater Honorary Professor, University of Bologna, Bologna, Italy

A few words on our speakers

- ***Marco Tartaglia*** *- Head of Molecular Genetics and Functional Genomics, Research Division, Ospedale Pediatrico Bambino Gesù, IRCCS, Roma, Italy*
- ***Thomas Edouard*** *- Endocrine, Bone Diseases, and Genetics Unit, Children's Hospital, Toulouse University Hospital, Toulouse, France*
- ***Federica Tamburrino -*** *Rare Disease Unit, Department of Pediatrics, IRCCS Policlinico di Sant'Orsola, Bologna, Italy*
- ***Alexander A L Jorge*** *- University of São Paulo (USP), Head and Principal Investigator of the Genetic Endocrinology Unit at Hospital das Clínicas, University of São Paulo, São Paulo, Brazil*

Agenda

1. ‘The molecular genetics of RASopathies’, Marco Tartaglia
2. ‘Growth and growth therapies in RASopathies’, Thomas Edouard
3. ‘Puberty in RASopathies’, Federica Tamburrino
4. ‘Metabolic Profile in Patients with Noonan Syndrome’, Alexander A L Jorge

- Conclusion with speakers and moderator

Topic 1- The molecular genetics of RASopathies

Noonan Syndrome

An Update and Review for the Primary Pediatrician

Jacqueline A. Noonan, M.D.

Introduction

Noonan syndrome[1] is a relatively common multiple congenital anomaly syndrome, with an estimated incidence of between one per 1,000 and one per 2,500 live births.[2] Affected individuals have characteristic facial features, are usually short in stature with a chest deformity, and about half have a congenital cardiac abnormality. Autosomal dominant inheritance, with variable expression, has been documented in a number of families. Many cases, however, appear to be sporadic. The diagnosis rests solely on clinical criteria, and so far, the underlying cause or genetic defect is unknown.

The natural history of this syndrome is still being defined. Children with Noonan syndrome have a large number of potential health problems, making it essential for the primary-care pediatrician to be aware of this syndrome, so that the special needs of such children may be met.

History

In 1883, Kobylinski[3] reported a 20-year-old male with clinical features compatible with what is now called Noonan syndrome. Many early publications reported both males and females with a webbed neck, small stature with low-set ears, micrognathia, and other anomalies which probably represented a number of different syndromes including Noonan syndrome. In 1930, Ullrich[4] described a number of patients with webbed neck and short stature, some of whom represented Turner syndrome and, no doubt, some Noonan syndrome. While Ullrich was intrigued primarily by the webbed neck, in 1938, Turner[5] described a number of patients with sexual infantilism who also had a webbed neck and short stature. Turner syndrome was later recognized as a sex chromosome abnormality with either the absence or an abnormality of one of the X chromosomes. Ullrich was intrigued by the work of a mouse geneticist, Bonnevie, who had bred a mutant strain of mice with a webbed neck and swelling of the limbs. In 1949, Ullrich[6] speculated on the possible similarity between his patients and the mice bred by Bonnevie. The term Bonnevie-Ullrich syndrome became popular, particularly in Europe, and was used to describe children, some of whom would now be recognized as having Noonan syndrome. In 1943, Flavell[7] reported a male who had a phenotype similar to that reported by Turner, and he used the term "male Turner" syndrome. In 1963, Noonan and Ehmke[8] reported nine patients — six males and three females, with short stature and characteristic facies including hypertelorism, ptosis, and low-set ears — whom we felt represented a distinct syndrome. Several of the males had undescended testes. Chest deformities were frequent, and all had valvular pulmonary stenosis. Chromosome studies were normal. Dr. John Opitz[9] suggested the eponym Noonan syndrome be used to describe such patients. He felt my observation that this syndrome occurred in both males and females was not associated with chromosomal abnormalities and could be inherited justified the eponym. For a number of years, the term Turner phenotype persisted, but in 1968, the eponym Noonan syndrome appeared in print for the first time. Thereafter, Dr. Victor McKusick listed Noonan syndrome as a hereditary congenital disorder of the cardiovascular system. Since the eponym Noonan syndrome is relatively recent, many pediatricians have only a limited knowledge of this condition. This review is intended to be an update and review for the primary pediatrician.

Genetics

Because of the superficial resemblance between patients with Noonan syndrome and those with Turner syndrome, an abnormality of the X chromosome has been

Noonan syndrome

JUDITH E ALLANSON

From The Genetics Centre, Southwest Biomedical Research Institute, PO Box 8845, Scottsdale, Arizona 85252, USA.

Noonan syndrome was first described over 20 years ago by Noonan and Ehmke[1]; they defined a specific group of nine patients with valvular pulmonary stenosis who, in addition, had short stature, mild mental retardation, hypertelorism, and unusual facies. In retrospect, the first case was probably described by Kobylinski in 1883.[2] Since that time, over 300 cases have been reported in medical publications. The incidence of Noonan syndrome has been estimated to be between 1 in 1000 and 1 in 2500 live births.[3] The cardinal features of Noonan syndrome are short stature, congenital heart defect, broad or webbed neck, a peculiar chest deformity with pectus carinatum superiorly and pectus excavatum inferiorly, and characteristic facies, which alter predictably with age to produce a discrete but changing phenotype which is described and illustrated below. Good reviews of Noonan syndrome are to be found by Mendez and Opitz,[4] Nora *et al*,[5] Char *et al*,[6] and Pearl.[7]

Received for publication 22 April 1986.
Accepted for publication 2 May 1986.

Clinical features*

GROWTH

At birth the average length is 47 cm. Birth weight is generally normal (40%) but can be high, secondary to subcutaneous oedema. Prepubertal growth tends to parallel the 3rd centile (60%) with a relatively normal growth velocity. The pubertal growth spurt is often reduced or absent.[9] Delayed bone age has been reported in up to 20% of cases. Normal growth hormone levels with slightly raised somatomedin levels have been found in some patients.[10] Detailed growth curves for males and females with Noonan syndrome are now available.[11]

CRANIOFACIAL

In the newborn period the main features are hypertelorism with downward slanting palpebral fissures (95%), low set, posteriorly rotated ears with a thick helix (90%), deeply grooved philtrum with

*Incidence figures are derived from reviews by Mendez and Opitz,[4] Pearl,[7] and Allanson[8] unless specifically referenced.

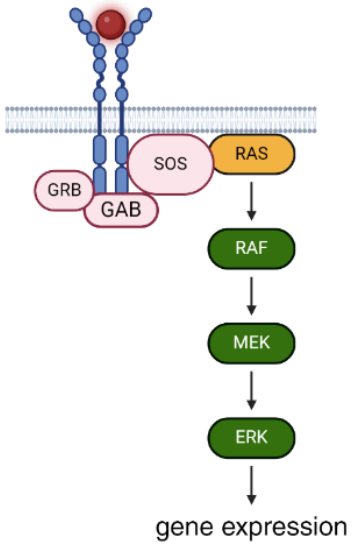
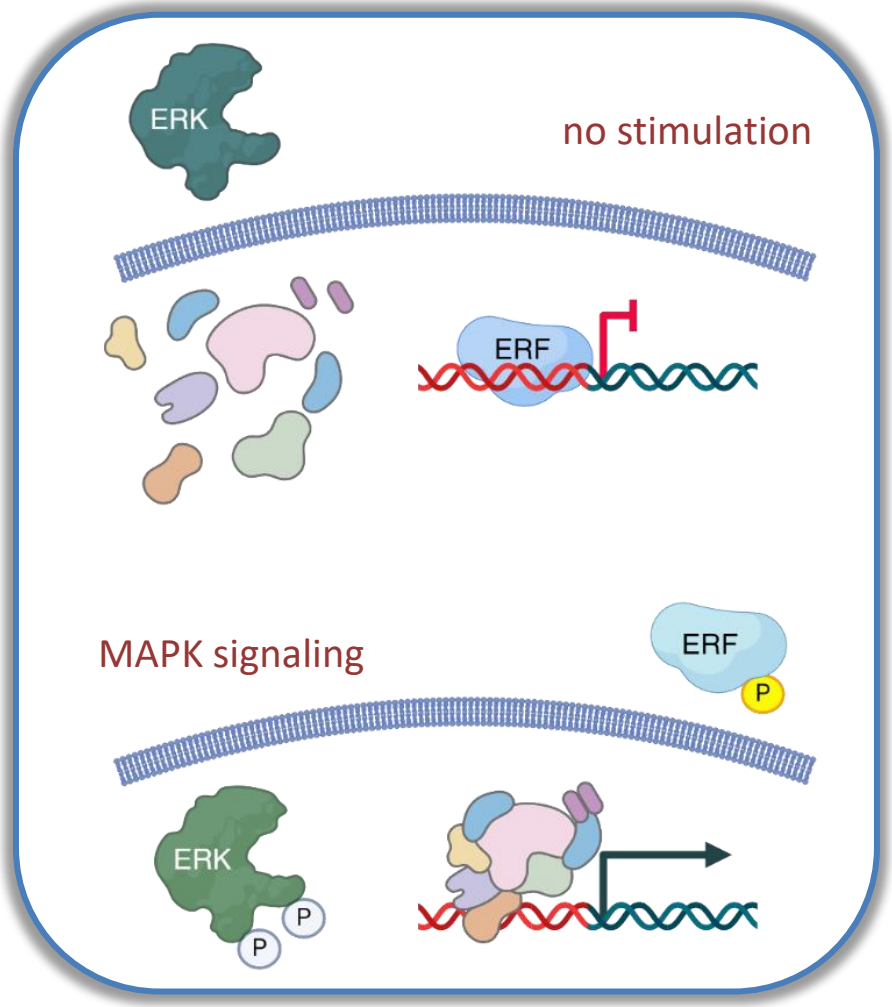
Dentici *et al., Eur J Hum Genet, 32:954-63.*

ERF & MAPK signaling

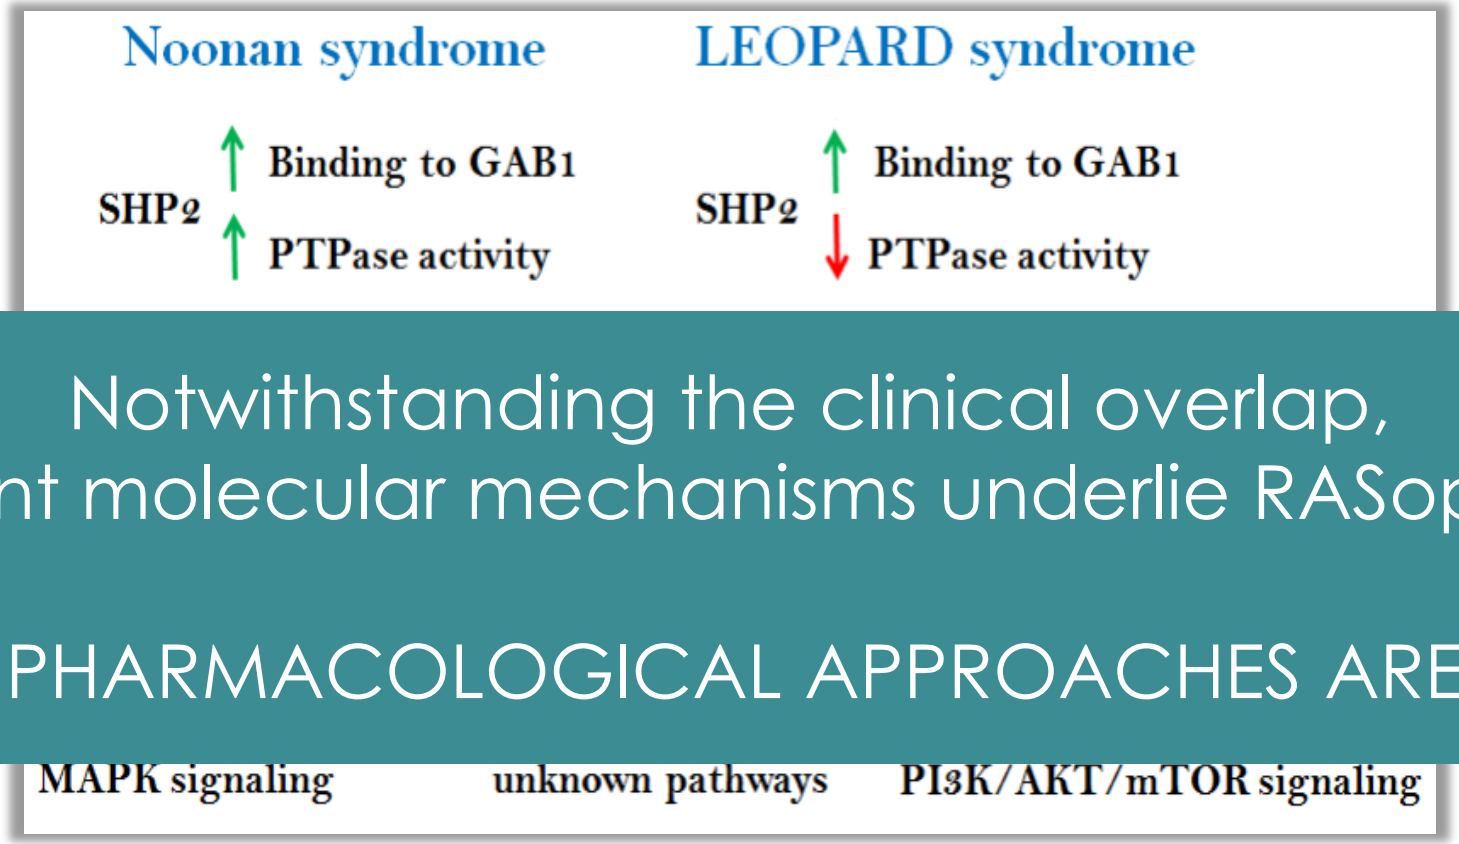




ERF is an ETS domain transcriptional repressor that binds to DNA in a sequence-specific manner to transcriptionally silence target genes

ERF is regulated by ERK phosphorylation via nucleo-cytoplasmic shuttling. ERK-mediated phosphorylation promotes ERF translocation to the cytoplasm, allowing transcription of target genes

Dentici *et al., Eur J Hum Genet, 32(8):954-963.*

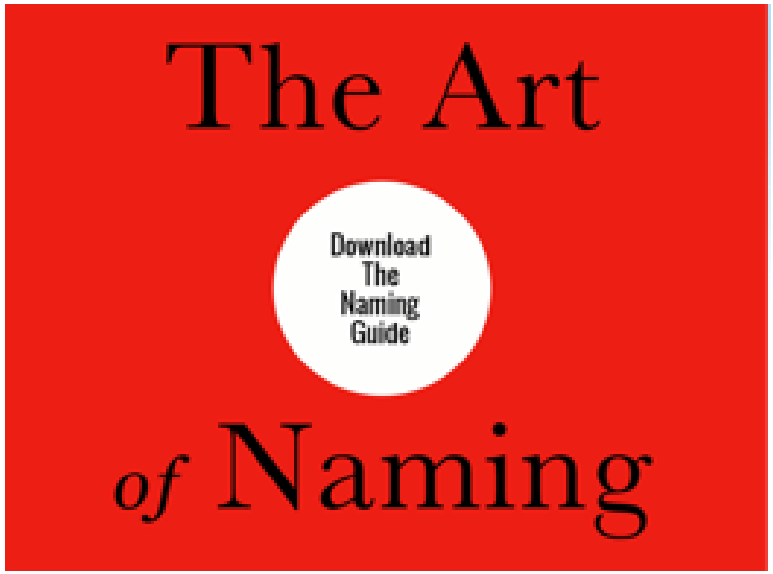


Notwithstanding the clinical overlap,
different molecular mechanisms underlie RASopathies

TARGETED PHARMACOLOGICAL APPROACHES ARE REQUIRED

- *Ptpn11*^{Q79R} e *Raf1*^{L613V} models:
The use of MEK inhibitors allows to rescue multiple clinical features (e.g., reduced growth, HCM)

- *Ptpn11*^{Y279C} model :
Rapamycin, an inhibitor of the PI3K-AKT-mTOR pathway, is effective in blocking HCM progression



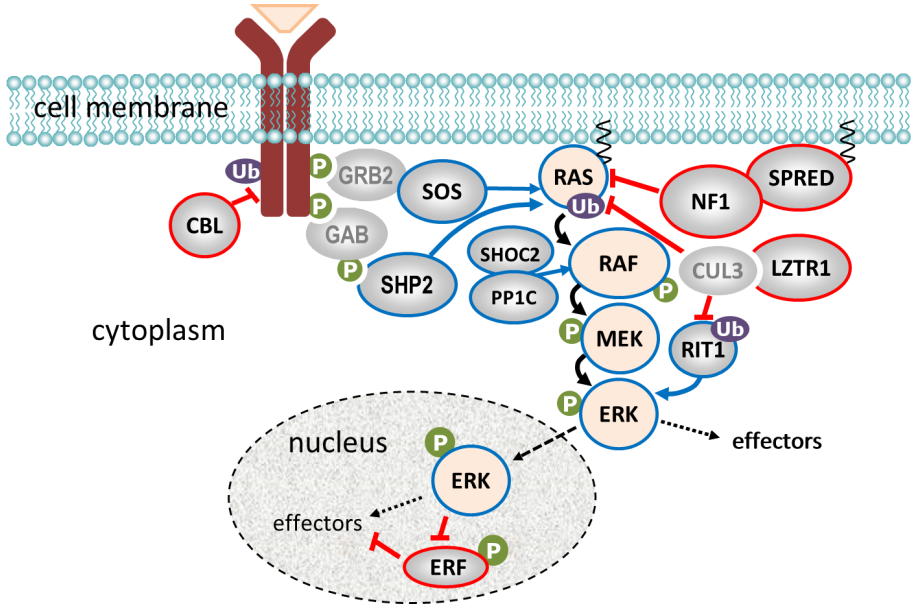
«Noonan syndrome» is not a clinically exhaustive term

the involved gene and pathogenic variant(s) should be taken into account to effectively apply precision medicine and optimize patient management and care.

Take home message (1)

RASopathies share the upregulation of RAS-MAPK signaling as a common pathogenetic mechanism

>25 disease genes identified;
13 implicated in Noonan syndrome



New RASopathies and recessive forms are emerging

Take home message (2)

Mutations may affect protein function by multiple mechanisms and have different consequences on intracellular signaling

Other pathways contribute to the clinical phenotype and phenocopies do exist

RASopathy mutants are weak hypermorphs & mutations do not necessarily predispose to cancer

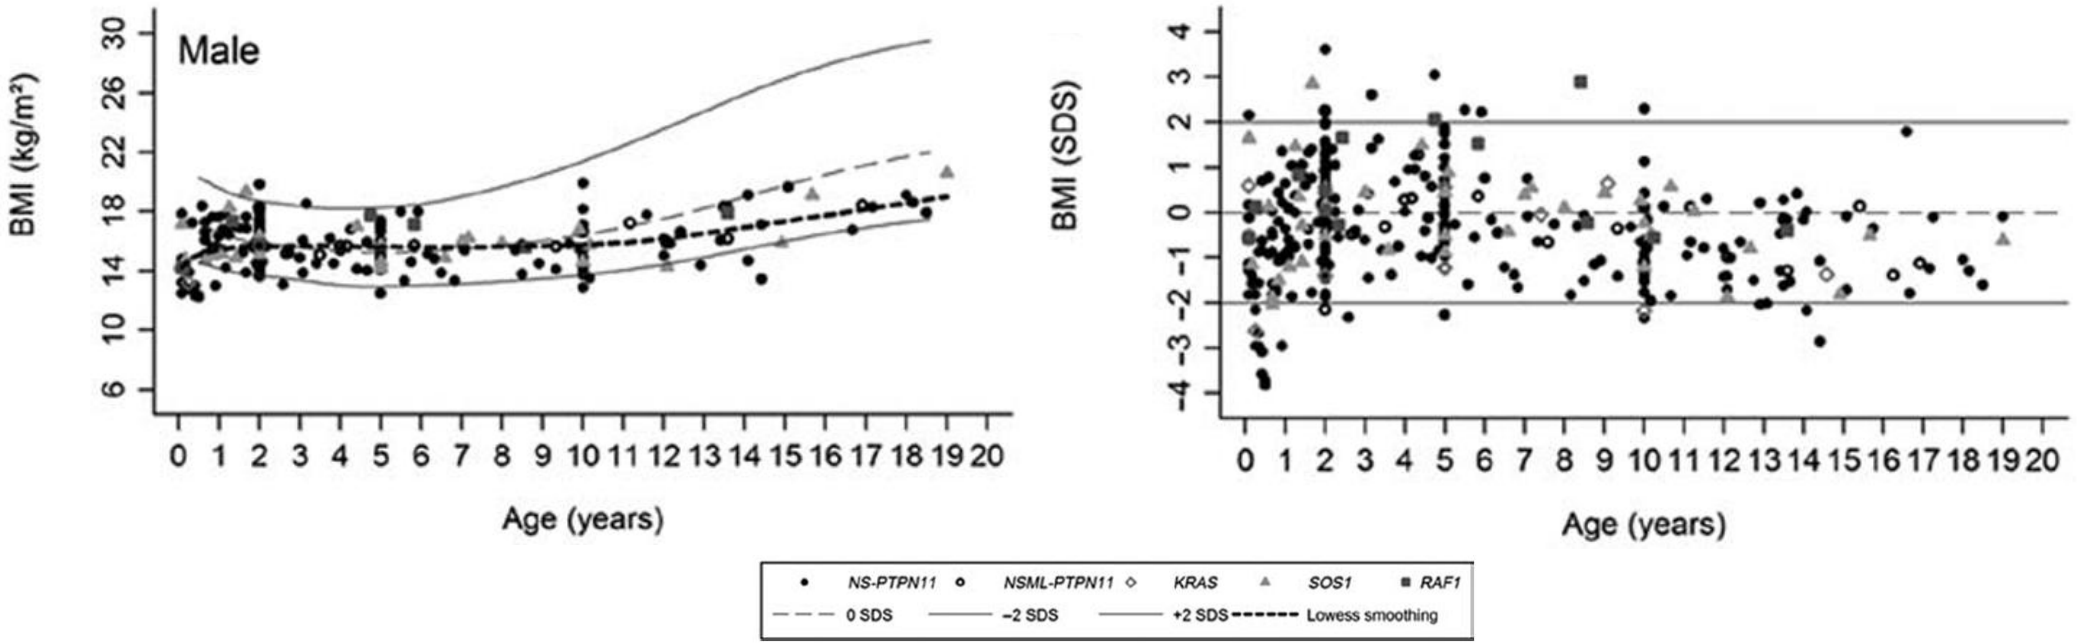
Nutritional and metabolic aspects

- **Feeding difficulties and failure to thrive** are frequent in newborns and infants (75%)
  - Poor sucking, prolonged feeding times, recurrent vomiting
  - Tube feeding needed in 25%
  - Usually resolves within the first few years of life

- **Lean phenotype** with BMI in the low–normal range

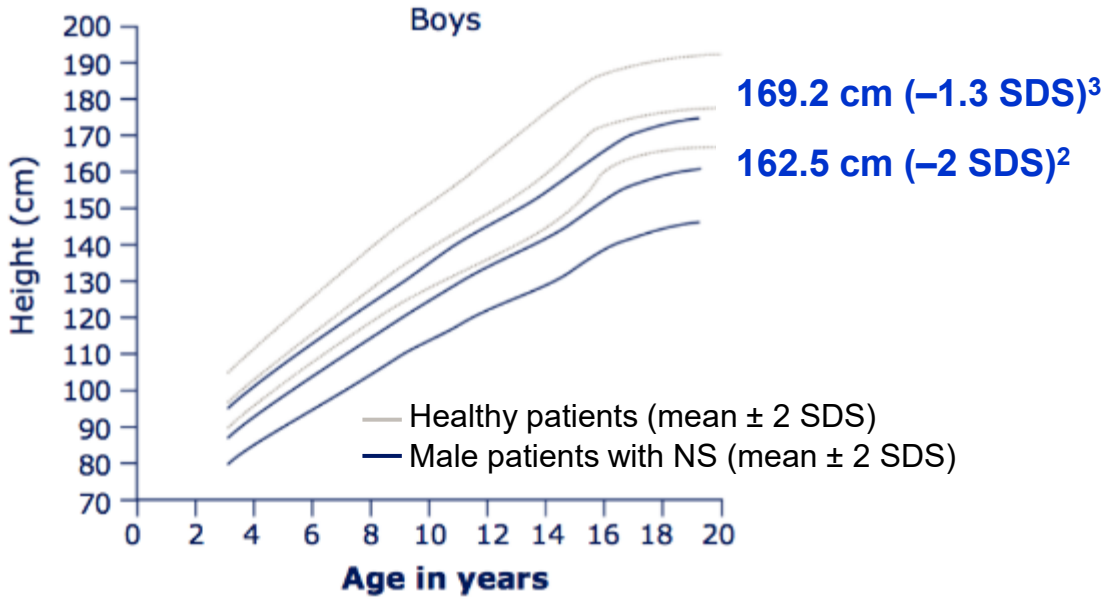
- Aetiology unknown, could be due to increased energy expenditure



Roberts AE et al. Lancet 2013;381:333–42; da Silva FM et al. Am J Med Genet A 2016;170:1525–31; Cessans C et al. Eur J Endocrinol 2016;174:641–50.

Growth and puberty

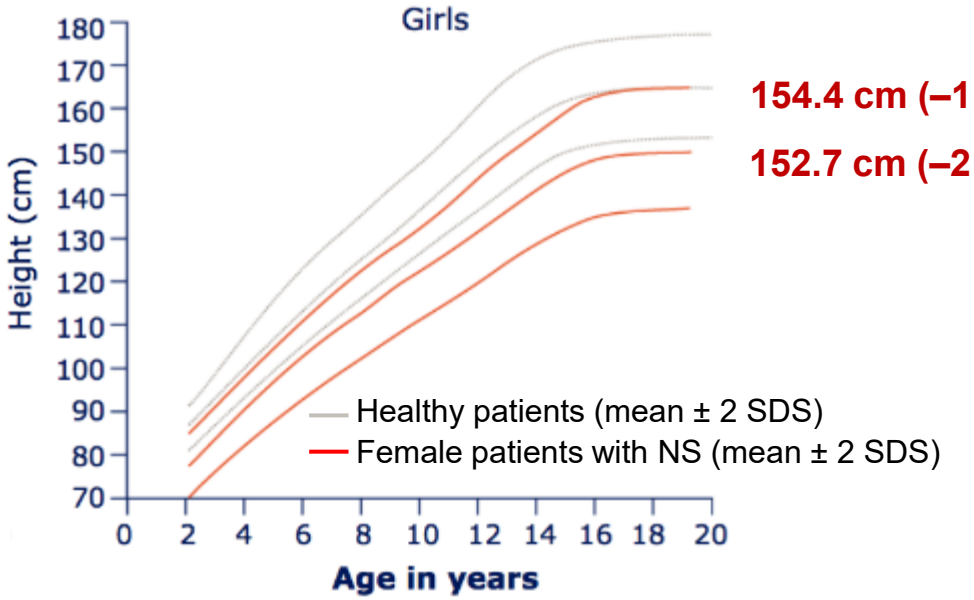
Short stature in 50–70% of patients with NS[1]



169.2 cm (–1.3 SDS)[3]

162.5 cm (–2 SDS)[2]

Adapted from Ranke et al. 1988[2]



154.4 cm (–1.7 SDS)[3]

152.7 cm (–2 SDS)[2]

Adapted from Ranke et al. 1988[2]

- Birth length in the lower normal range (25% small for gestational age)
- Decreased growth velocity and short stature by 2 years of age
- Worsening during puberty due to delay
- Bone age typically delayed by about 2 years, allowing for prolonged catch-up growth

1. Edouard T et al. Eur J Med Genet 2022;65:104404; 2. Ranke MB et al. Eur J Pediatr 1988;148:220–7; 3. Binder G et al. J Pediatr 2012;161:501–5.

Weekly Somapacitan is Effective and Well-Tolerated in Children with Noonan Syndrome: Randomised Phase 3 Trial

Alexander A. L. Jorge[1], Assunta Albanese[2], Michael Højby[3], Kamil Soltysik[3], Thomas Edouard[4, 5], Anna Grandone[6], Michael Tansey[7], Jun Mori[8]

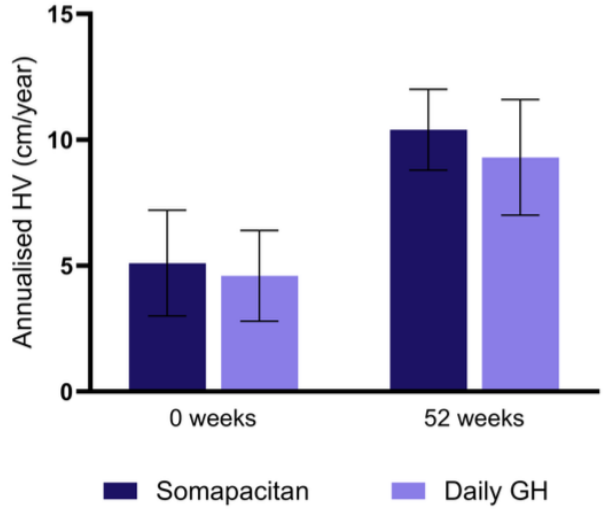
ABSTRACT CODE: LB91

In 77 patients with NS and short stature,

treatment over 1 year with daily somatropin (50 µg/kg/day) or

weekly somapacitan (0.24 mg/kg/week)

Figure 2 - Observed height velocity from baseline to week 52.



Error bars represent SD.

Table 2 - Statistical analyses of in-study efficacy endpoints at week 52

	somapacitan 0.24 mg/kg/wk estimated mean	daily GH 0.050 mg/kg/d estimated mean	ETD (95% CI)
Annualised HV, cm/y	10.4	9.2	1.2 (0.32 to 2.03)
Change in HSDS from baseline	1.07	0.75	0.32 (0.16 to 0.48)
Change in HVSDS from baseline	6.30	5.24	1.06 (0.01 to 2.10)
Change in IGF-I SDS from baseline	2.35	1.51	0.84 (0.36 to 1.31)
Change in BA/CA ratio	0.02	0.03	-0.01 (-0.06 to 0.03)

Full analysis set (all randomised participants).

Jorge A et al. Presented at the Joint Congress of ESPE and ESE 2025; 10-13 May 2025; Copenhagen, Denmark. Poster LB91.

Still many unanswered questions related to rhGH treatment for NS…

- What is the long-term efficacy of rhGH treatment on adult height?
- How safe is the treatment in patients with hypertrophic cardiomyopathy?
- Could there be genotype–phenotype correlations for rhGH treatment efficacy and safety?

- Is a GH stimulation test necessary in children with short stature?
- Should a brain MRI be performed before initiating rhGH treatment?
- What is the optimal age to start rhGH therapy?
- What height threshold should be used when considering rhGH treatment?
- Could rhGH have a beneficial effect on muscle function and motor development?

➢ **Consensus guidelines for Noonan syndrome spectrum disorders**

(currently being developed and validated in association with ESPE and ERN-ITHACA)

Take-home messages

- **NS is a common genetic disorder** that is now well described in childhood

- NS and related disorders are caused by **mutations in the RAS/MAPK signalling pathway**
  - ➢ The hyperactivation of this pathway is responsible for the different defects

- **Genotype–phenotype correlations** have been established

- **To date, only symptomatic treatments are available** (rhGH for short stature)
  - – Improves growth velocity and height SDS and increases IGF-1 levels in the medium term
  - – Some issues have to be resolved (adult height, patients with HCM, genotype–phenotype correlations…)

- **RAS/MAPK inhibitors or modulators** (i.e. MEK inhibitors, CNP analogues) are currently being assessed

Topic 3 - Puberty in RASopathies

Federica Tamburrino , MD, PhD, Rare Disease Unit, Department of Pediatrics, IRCCS Policlinico di Sant'Orsola, Bologna, Italy

PUBERTY

Puberty is a process that marks the transition from childhood to adulthood, and influences the development of secondary sexual characteristics, reproductive organs, growth velocity and final height (FH), and self-esteem

OUTLINE

- The challenge of puberty in RASopathies
- Noonan syndrome as a model
- Extending to other conditions
- What we know about the mechanisms
- What clinicians should do
- What still needs to be learned
- Take home messages

1. The Challenge of Puberty in RASopathies

What is known from the literature regarding puberty in RASopathies?

- Delayed Puberty is frequent
- Pubertal Onset is usually spontaneous
- Sex Differences
- Impact on Final Height and Psychosocial well-being
- Hormonal Alterations affecting fertility

European Reference Networks ITHACA

2. Noonan syndrome as a model

⏱️ 🔹 Delayed Puberty

- **Pubertal onset:** typically delayed by ~2 years (not in all patients)
- **Growth during puberty:** secondary peak growth rate lower than general population (GP)
- Multiple cases of **delayed puberty** described **and primary amenorrhea** reported in some cases
- **Puberty progression:** in some patients, **onset is within normal range** but **progression is slow**

Shaw AC et al, 2007
Romano AA et al, 2009
Rezende et al, 2022
Libraro et al. 2021

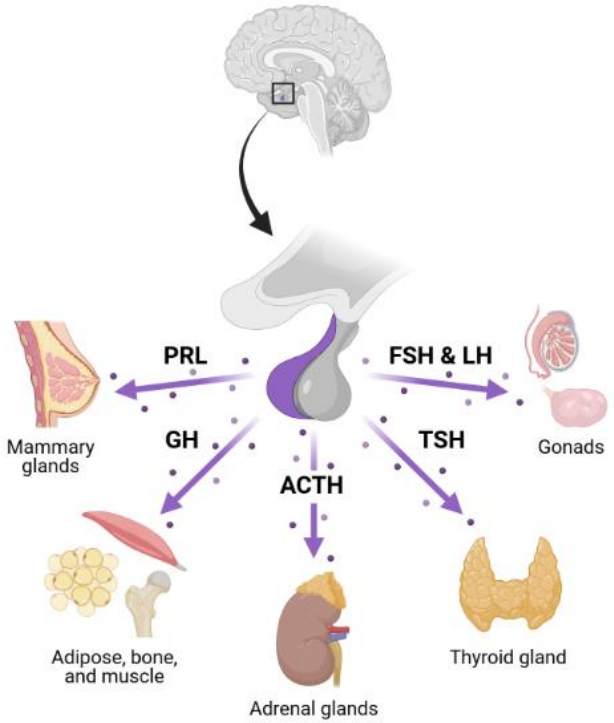
	Age at start puberty			
	Males		Females	
	Age	% delay	Age	% delay
Shaw et al., 2007	14.5 yrs (10-18)		14 yrs (10-18)	
Romano et al., 2009	> 13.5 yrs	35%	> 13 yrs	44%
Libraro et al., 2021	12.1±2.3 yrs	10%	12.1±1.3 yrs	45%
Rezende et al., 2022	12.5±1.7 yrs	27.9%	11.9±1.9 yrs	49.1%
Patti et al., 2024	12.3 yrs±2.7 DS		13.3±0.8 yrs	
Tamburrino et al., 2025	11.96±0.17 yrs	2.6%	12.92±0.25 yrs	23%

🔔🔹 Pubertal Onset

- Despite the delay**, puberty begins spontaneously** in most NS patients, indicating normal hypothalamic-pituitary function
- Consider:
  - mild alteration in GnRH pulsatility
  - partial pituitary resistance to GnRH

↓

delay in HPG axis maturation



Sex differences

Females

- **Puberty onset:** more often delayed compared to males
- **Fertility:** generally preserved

Males

- **Puberty onset:** may be delayed
- **Cryptorchidism:** present in 60–77% of patients
    - Similar frequency in normal and delayed puberty groups
    - **Impact on puberty:** minimal
    - **Impact on fertility:** can impair spermatogenesis
- **Fertility:** reduced (not limited to pts with cryptorchidism); exact prevalence unknown

Rezende et al., 2022
Tamburrino et al., 2025

📈 🔹 Impact on Final Height and Psychosocial Development

- The **age of onset** and the **duration** of pubertal development significantly **influence** the **growth spurt and near adult height** in RASopathies, exacerbating the typical growth deficits associated with these conditions.

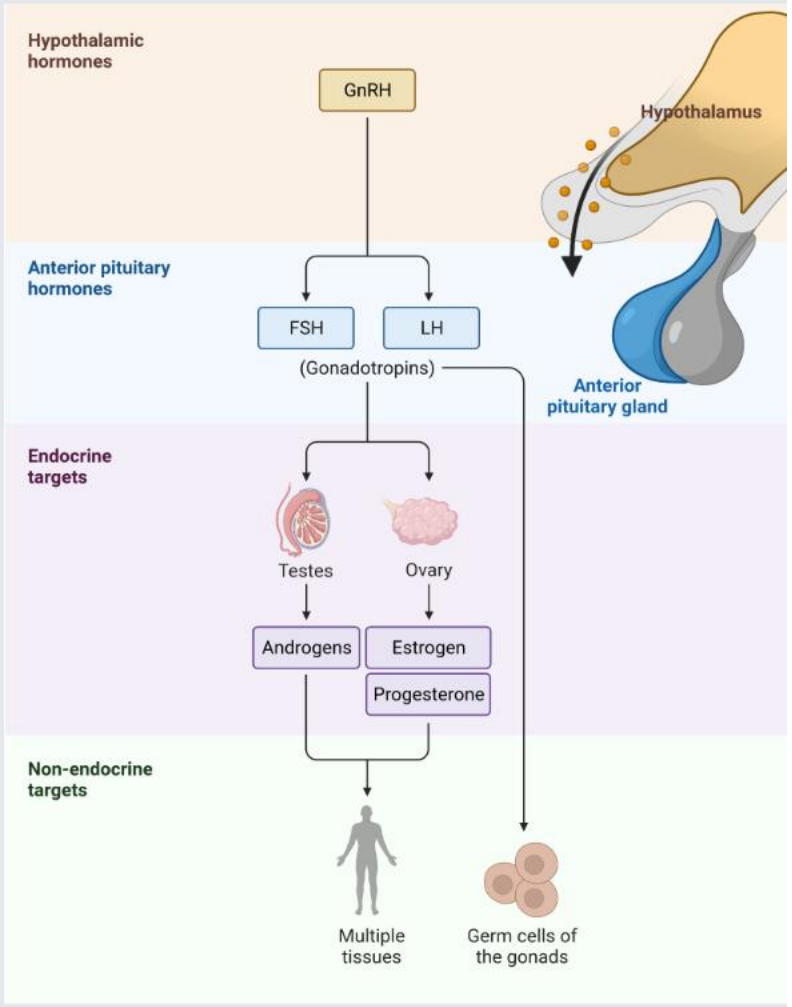
- In RASopathies, **delayed pubertal development and inadequate pubertal catch-up growth** could contribute to the observed **reduced adult height**

- **Emotional** and **social challenges** due to delayed development

Hormonal Alterations

- Altered levels of LH, FSH, and sex steroids reported in several studies

- Notably, in **males** with NS, **fertility** appears to be **reduced**, probably due to
  - the high incidence (60–77%) of cryptorchidism
  - primary alterations in the activity of Sertoli and Leydig cells



Ankarberg-Lindgren C et al 2011
Moniez S et al, 2018

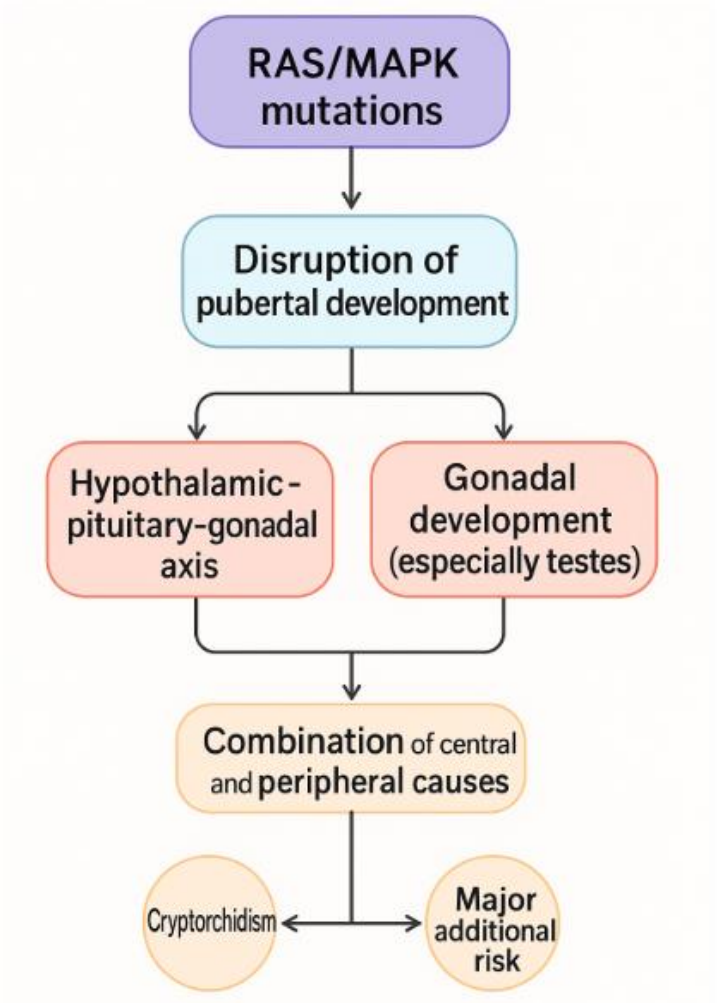
3. Extending to other conditions

Syndrome	Delayed Puberty	Precocious Puberty	Notes / Evidence
NSML	Possible / scarce data	Rare / unknown	Very limited case reports
Costello	Reported	Anecdotal	Mixed pattern, mostly delayed
CFC	Reported	Anecdotal	Possible hypogonadism, limited evidence

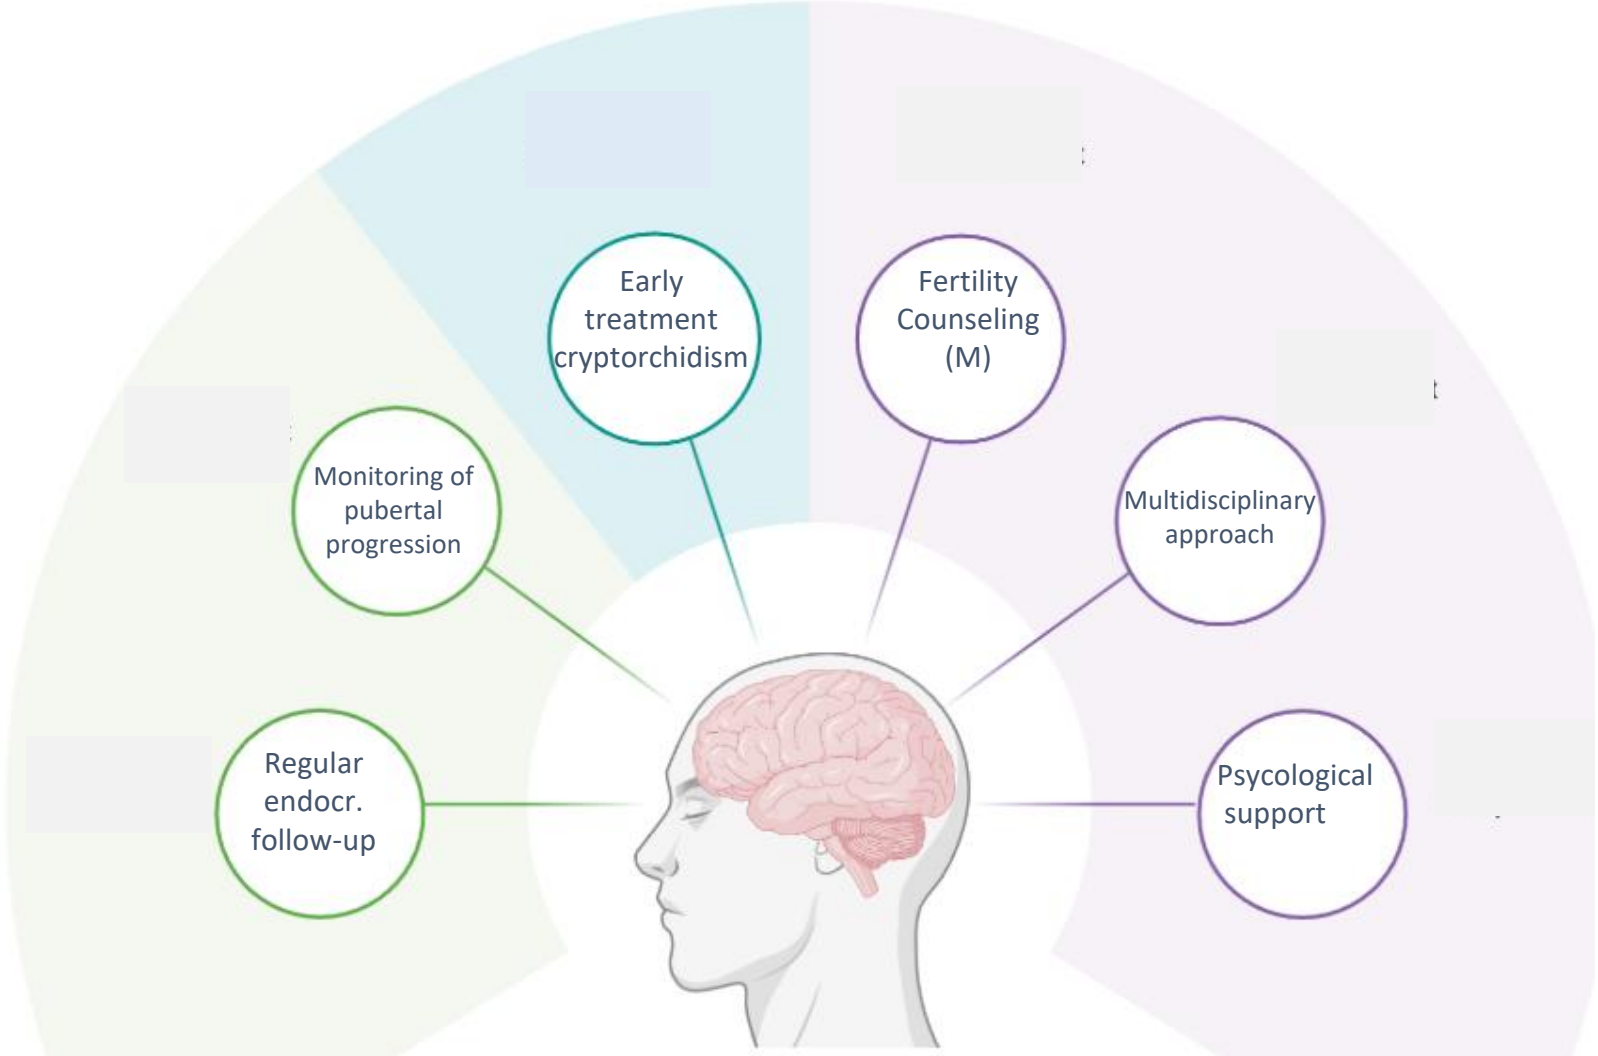
(Arnold-Chiari malformation, hyperprolactinemia, or GHD)

European Reference Networks ITHACA

4. What We Know About the Mechanisms

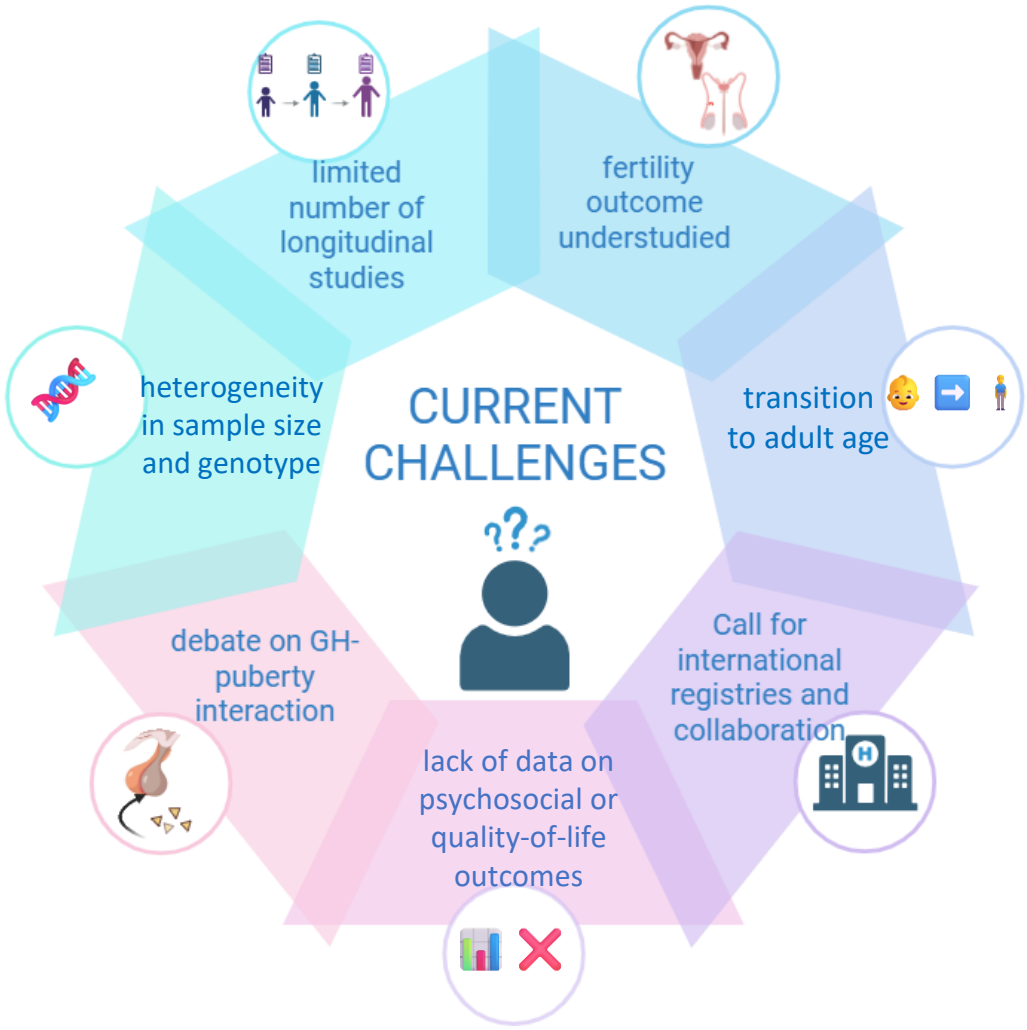


5. What Clinicians Should Do



European Reference Networks ITHACA

6. What still need to be learned



Personal data

Impact of pubertal timing on growth progression and final height in subjects affected by RASopathies

Spurt gain (cm)	21.5 [15.7, 25.4]	25.7 [16.9-33.4]	0.286
Final height (cm)	157.8 [148.5-165.8]	159.9 [154.4-164.0]	0.653
Final height SDS	-2.2 [-2.6, -1.5]	-1.7 [-2.3, -0.7]	0.286
Target height (cm)	166.5 [160.0, 171.0]	161.75 [158.0-167.5]	0.417
Pubertal timing, n (%)			0.118 ^
■ normal	15 (71.4%)	3 (60.0%)	
■ delayed onset	5 (23.8%)	0	
■ delayed completion	1 (4.8%)	2 (40.0%)	

GH, growth hormone; pts, patients; PHV, peak of height velocity, yrs, years.
Mann-Whitney test except ^ (Fisher's exact test).

Take Home Messages: Puberty and Growth in RASopathies

Delayed puberty onset
- negatively affects final height; insufficient pubertal growth spurt

Puberty generally starts spontaneously

Careful monitoring of growth and pubertal progression
- to optimize therapeutic interventions and improve final height outcomes

Research gaps remain
- need for further studies

Post-natal growth in NS

Age	Height SDS
1mo – 2y	-1.9 ± 1.6
2y - 5y	-2.0 ± 1.2
5y – 10y	-2.1 ± 1.1
12y - 18y	-3.2 ± 1.3

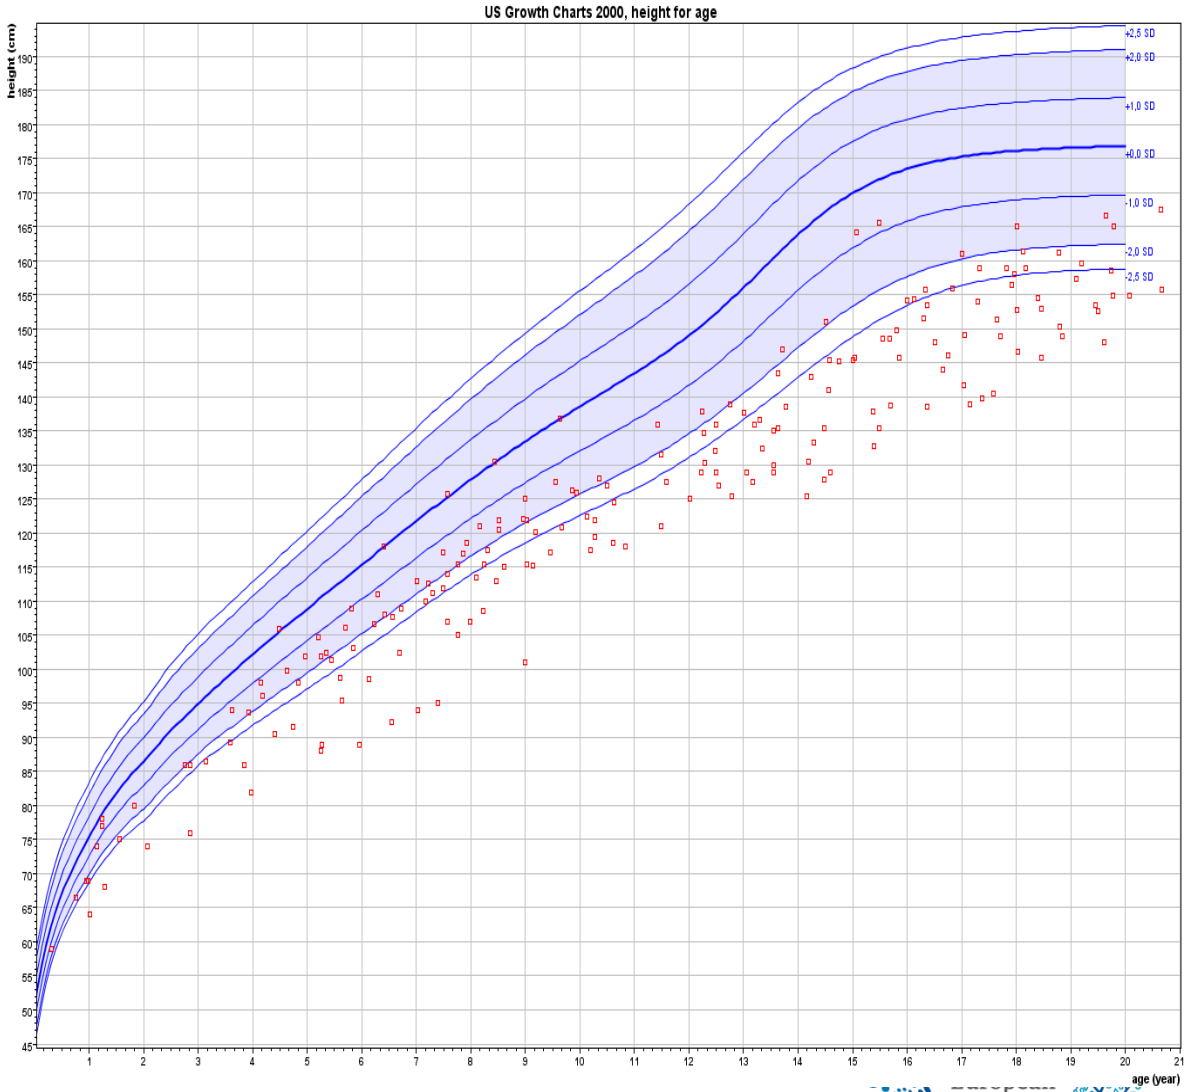
Total of 137 patients

Adult height (n = 60)

Males = 157.2 ± 7.5 cm

Females = 150.6 ± 7.7 cm

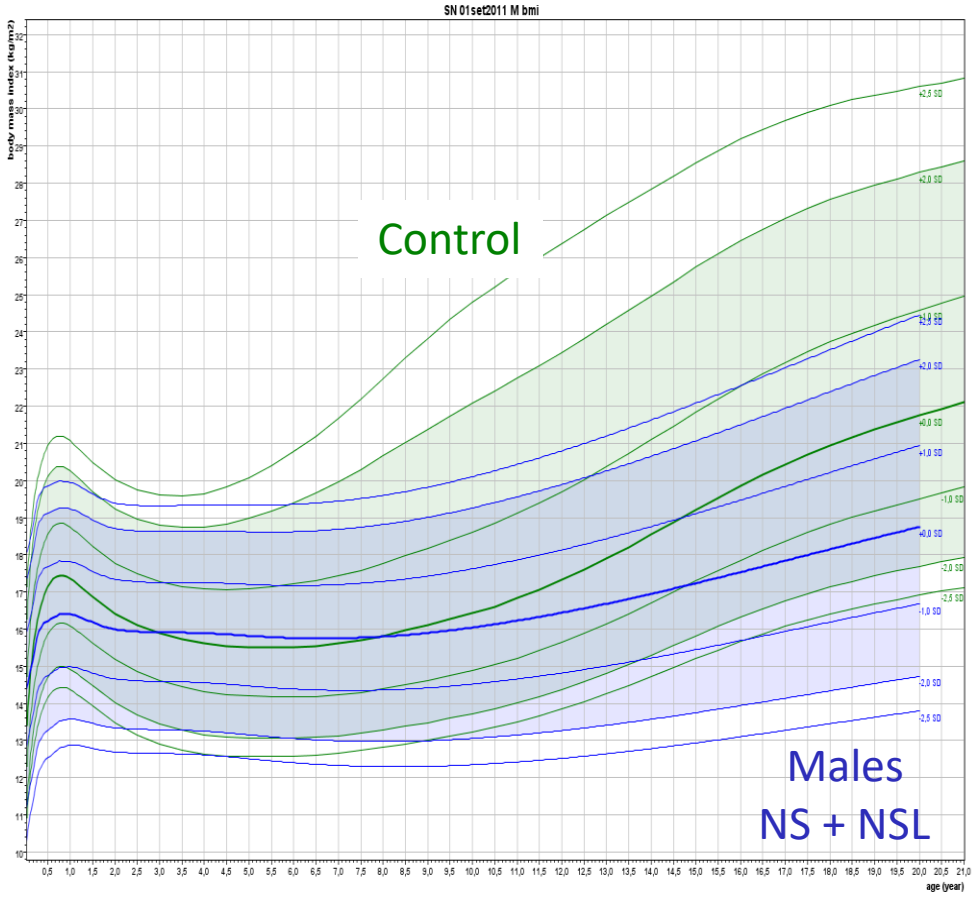
Our cohort was shorter in stature than the average normal Brazilian population, corresponding to a height SDS of **-2.6** and **-2.0** for males and females, respectively.

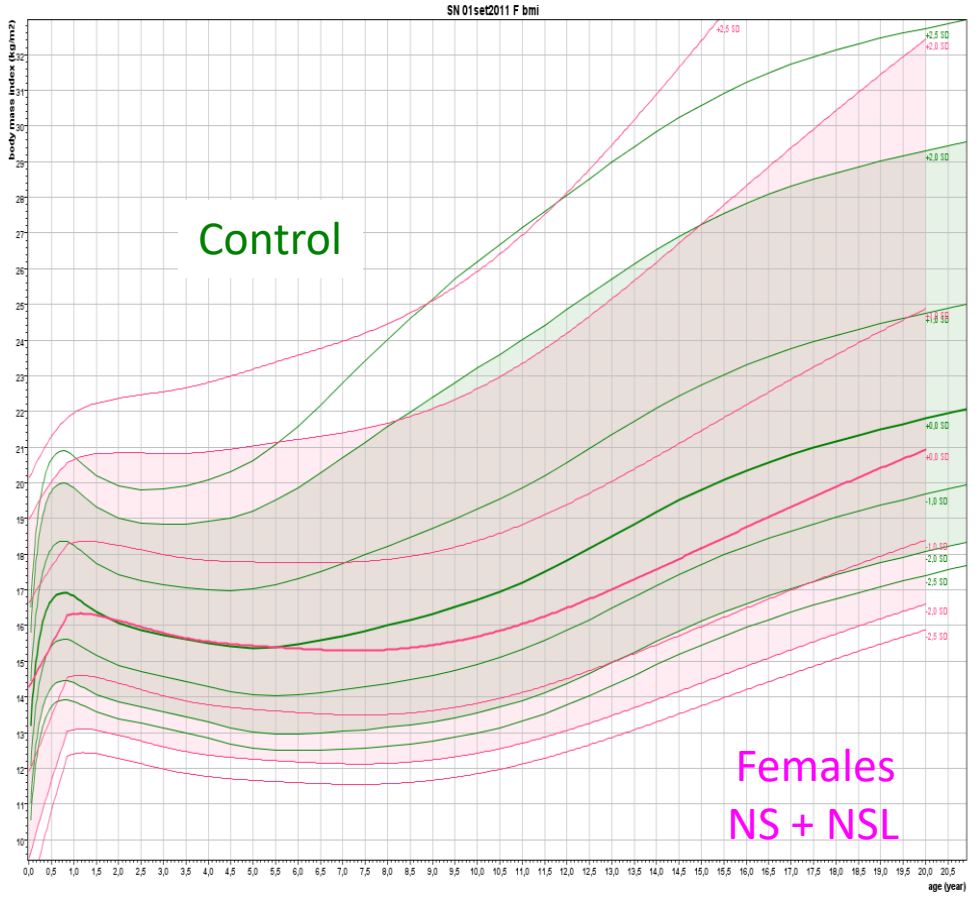


Malaquias *et al*. Am J Med Genet A. **2012** PMID: **22887833**

Post-natal growth curves in NS

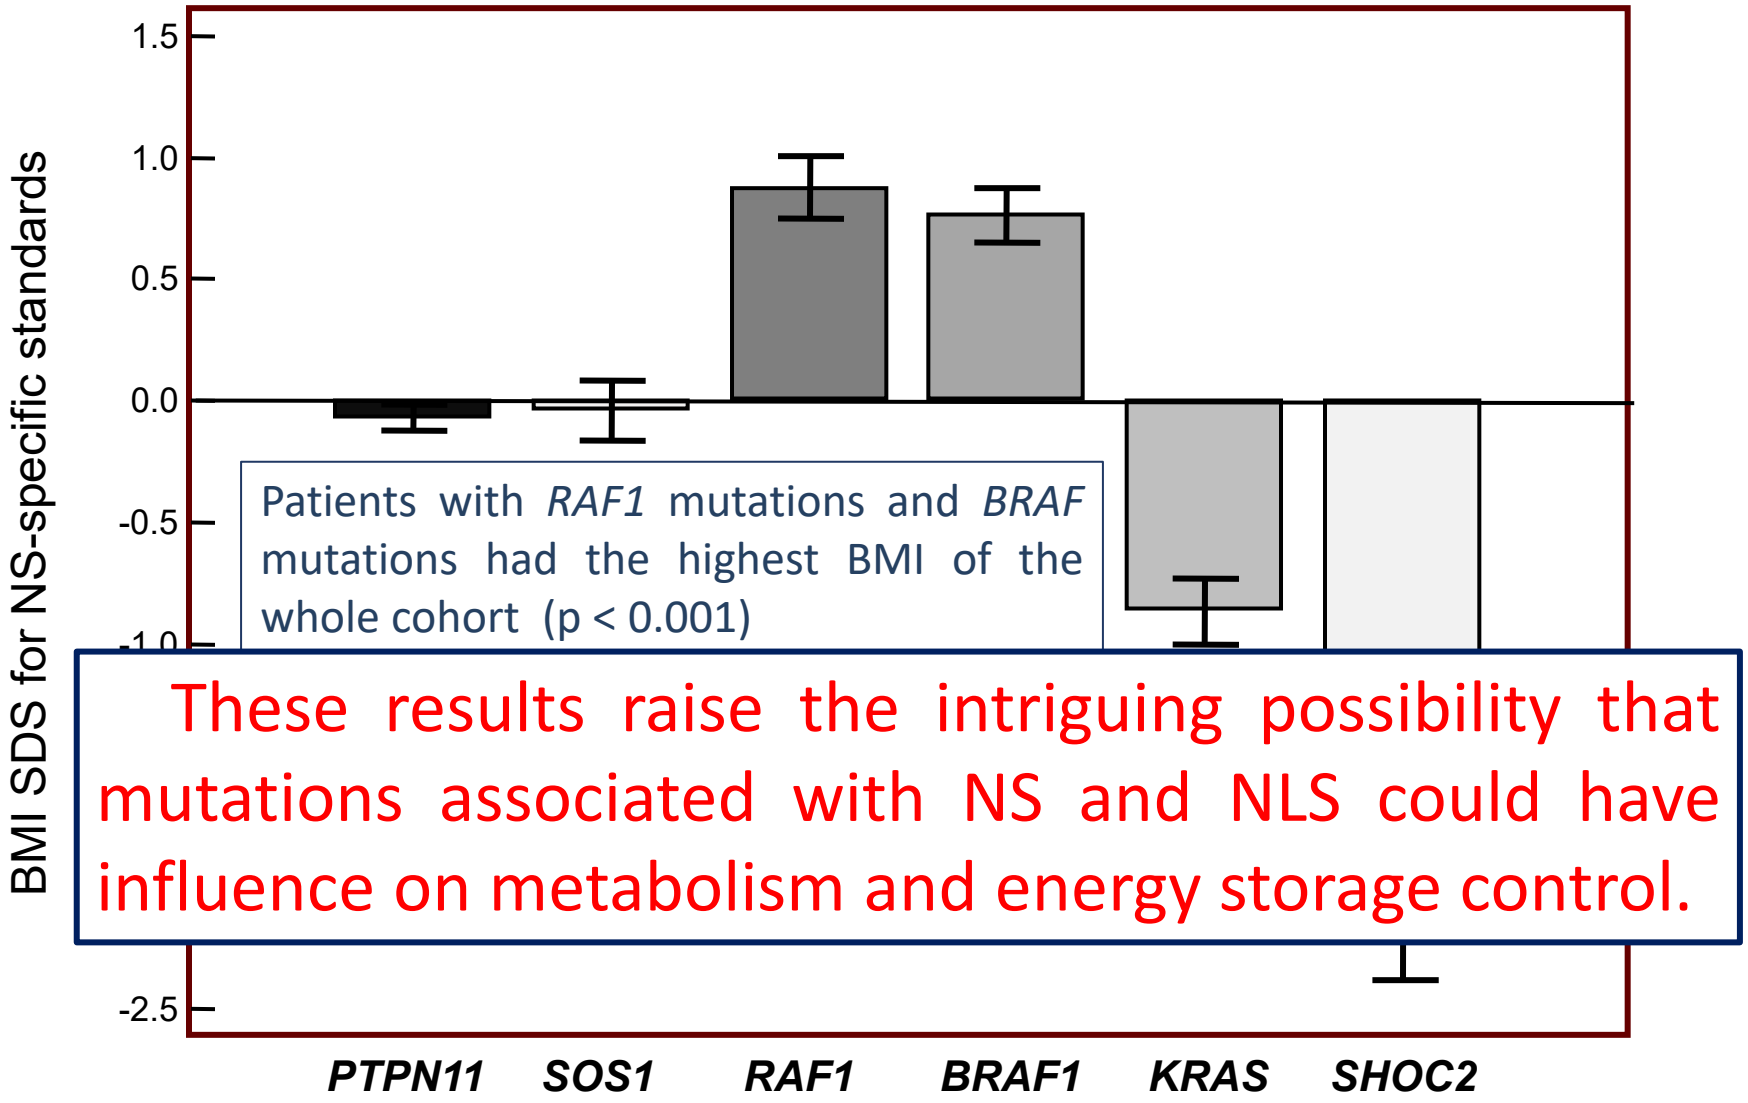
The mean BMI observed values correspond to -1.2 and -0.7 SDS for Brazilian healthy men and women, respectively





Malaquias *et al*. Am J Med Genet A. **2012** PMID: **22887833**

NS genotype influence on BMI



These results raise the intriguing possibility that mutations associated with NS and NLS could have influence on metabolism and energy storage control.

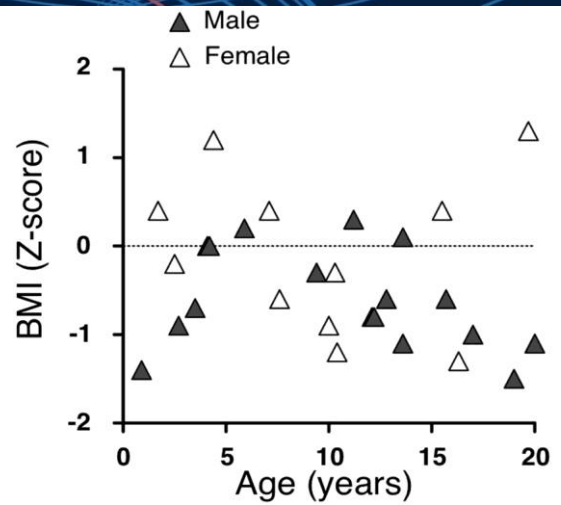
Malaquias *et al*. Am J Med Genet A. **2012** PMID: **22887833**

European Reference Networks ITHACA

Low BMI as NS-phenotype

One study evaluated 45 adults with NS and observed a lower incidence of overweight or obesity than observed in the general population (mainly among men).

Binder *et al.* J Pediatr **2012**; 161(3): 501-505

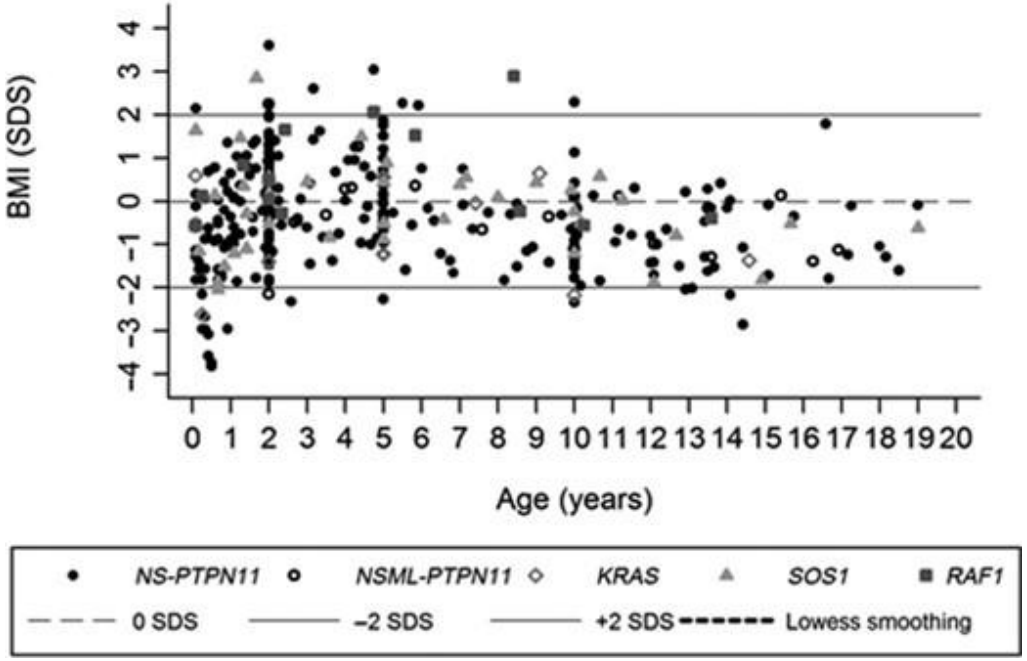


420 patients (176 females and 244 males)

- NS-PTPN11 n= 244
- NSML-PTPN11 n = 25

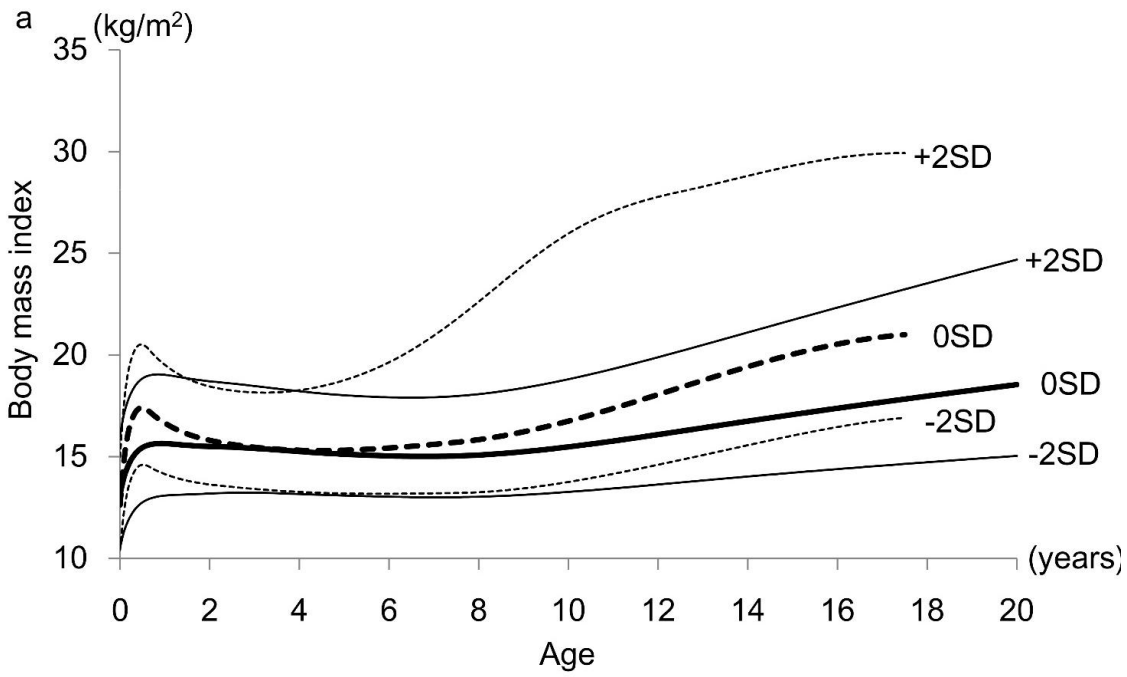
Patients with NS had lower BMI at 10 years.
No difference between genotypes was demonstrated

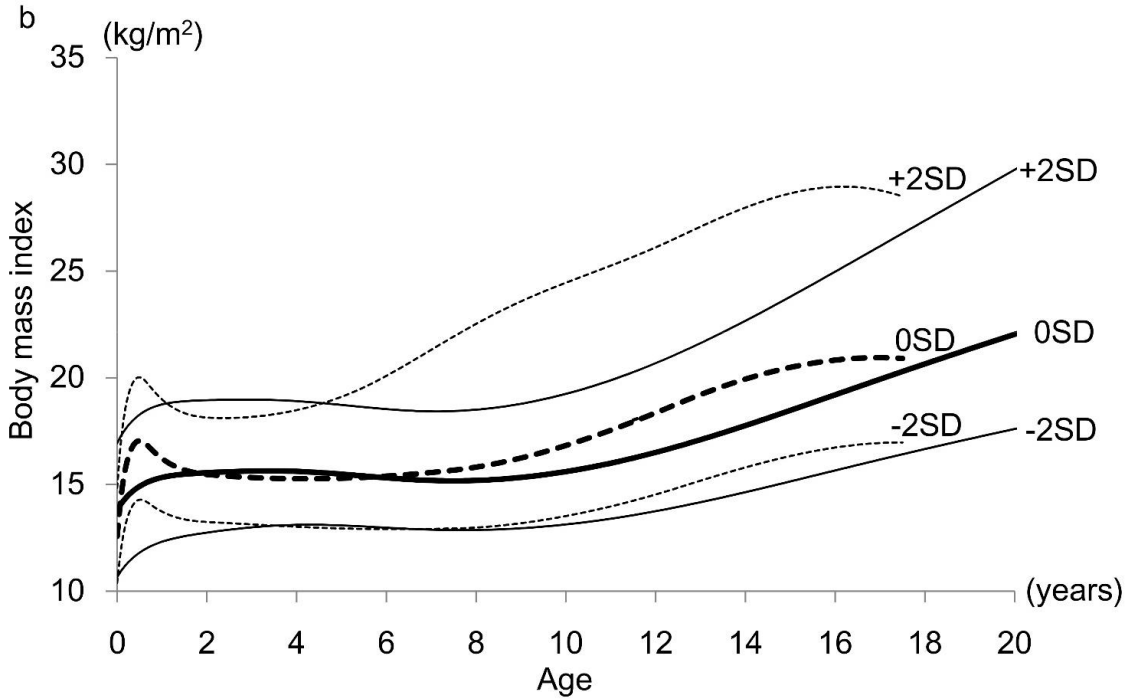
Cessans et al. Eur J Endocrinol. **2016**; PMID: 26903553



New BMI curves in patients with NS

308 subjects (males: 159 and females: 149)





Isojima et al. Pediatr Res. **2016**. PMID: 26650342

Additional BMI curves in patients with NS

190 patients

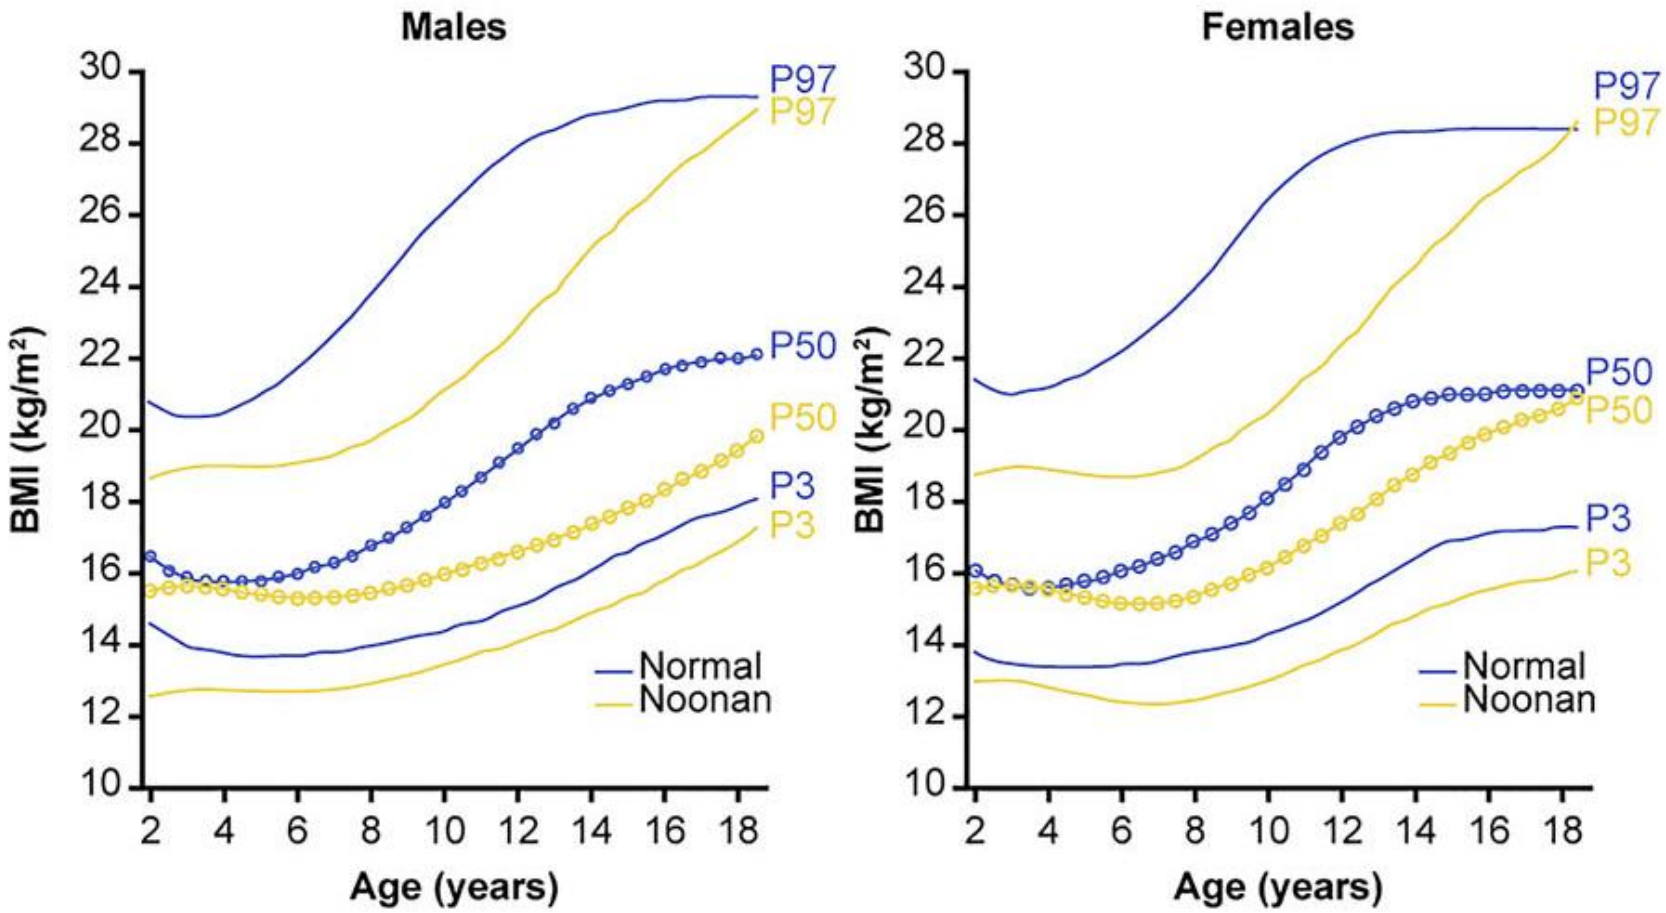
106 males : 84 females

66% *PTPN11*

BMI for both females and males with NS was below the reference curve for the general Italian population.

This trend was seen up to approximately 12 years of age, after which patients seemed to progressively gain weight.

Both females and males with *PTPN11* mutations had lower BMIs than those with “other mutations”,



Cappa et al. Horm Res Paediatr. **2024;** PMID: 38964306

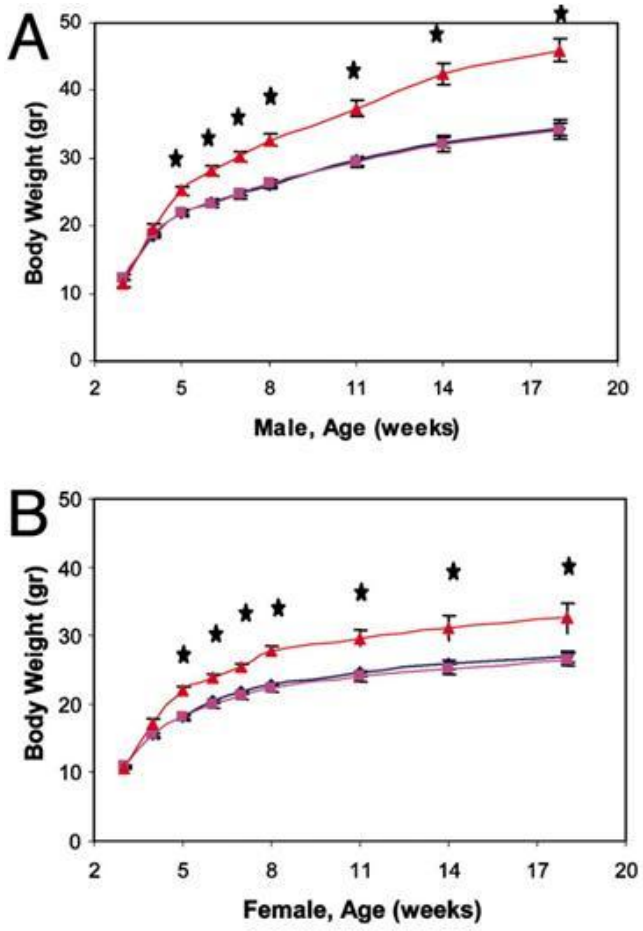
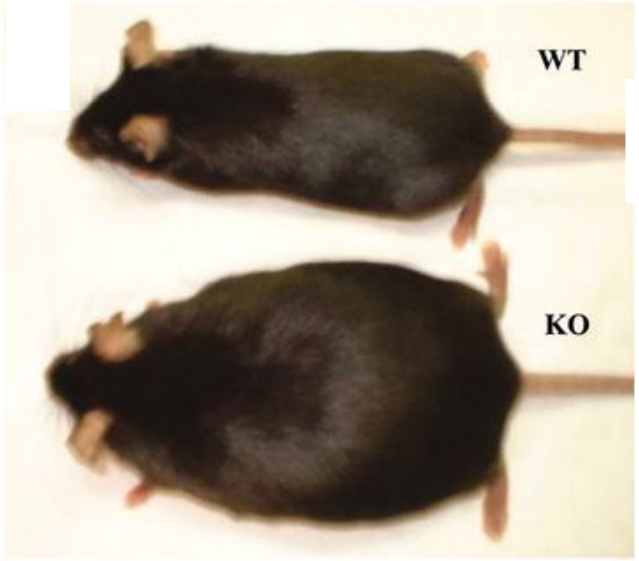
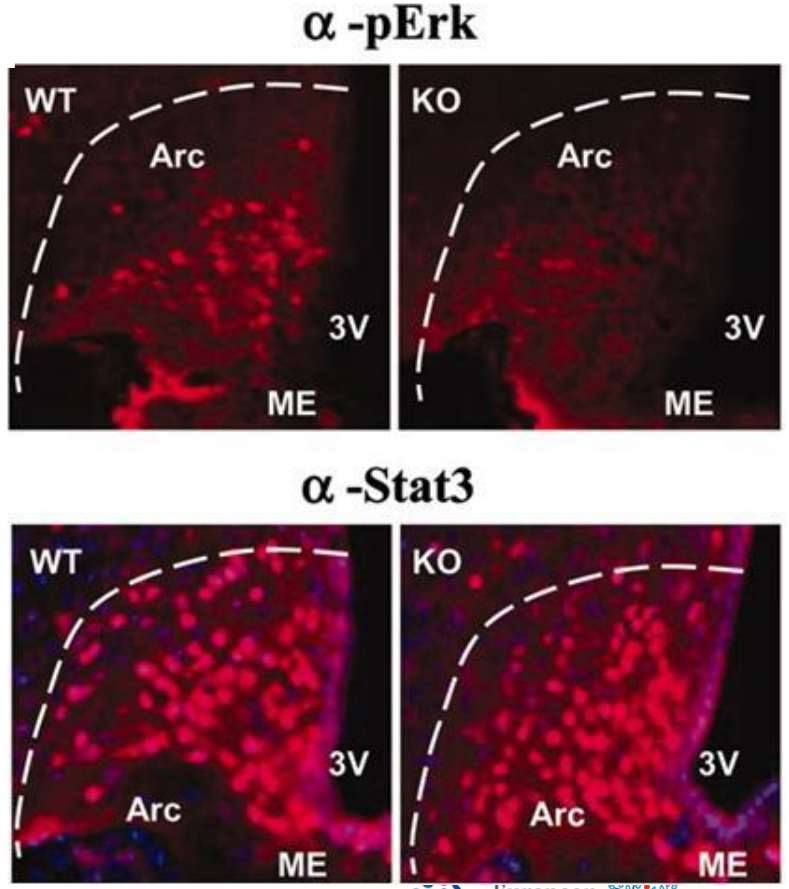
SHP2 controls energy balance and metabolism

Mice with selected deletion of Shp2 in forebrain neurons developed early-onset obesity, due to the decrease of leptin-stimulated Erk (MAPK) pathway







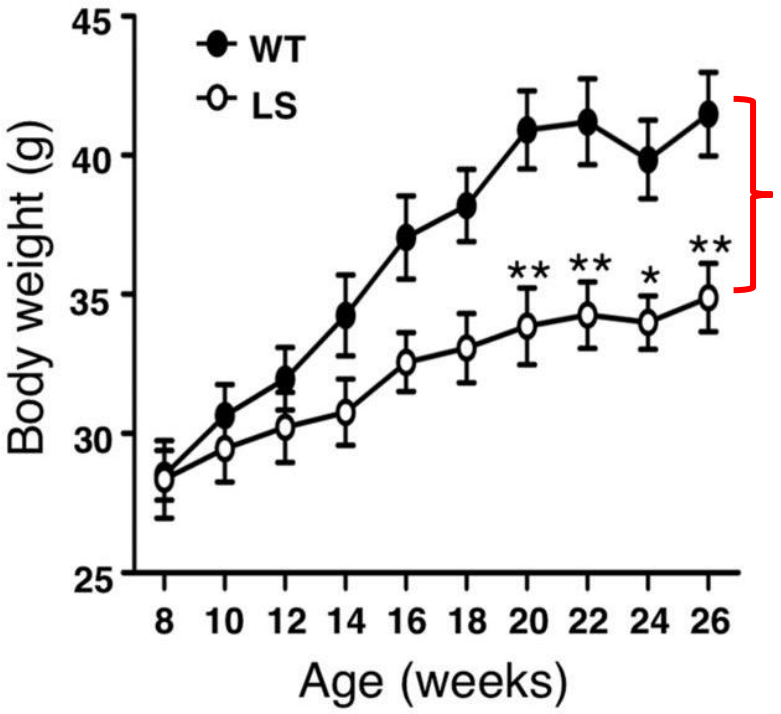
Zhang *et al.* PNAS **2004**; PMID: 15520383

Animal model with SHP-2 (*PTPN11*) mutation

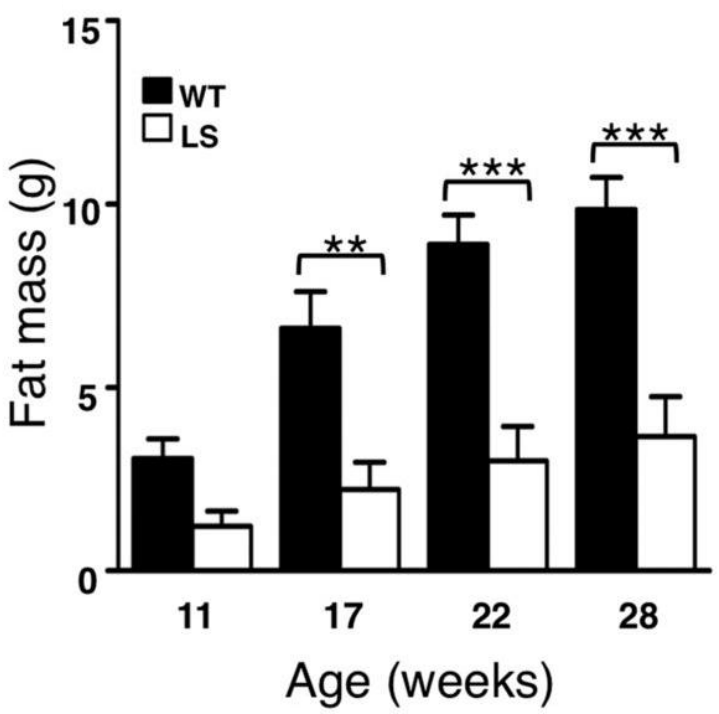
Knock-in mouse model carrying the T468M mutation (SHP2 mutations in Leopard syndrome/NSML patients)

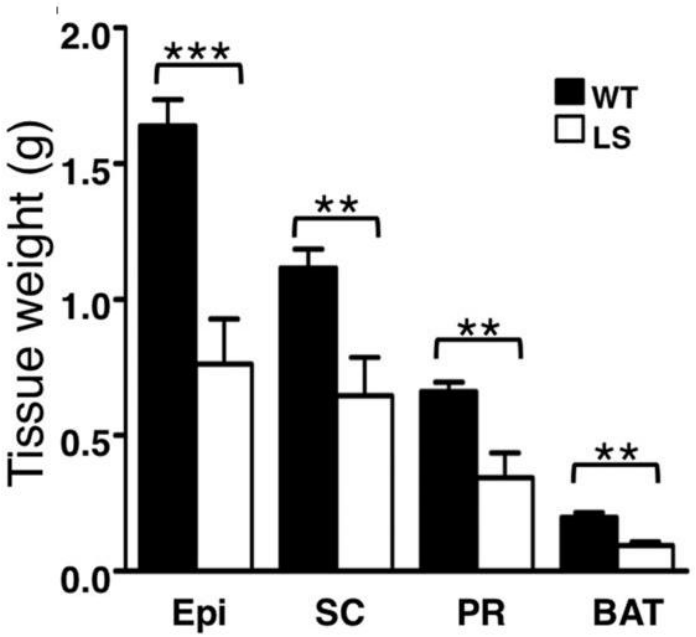
NS variants: **SHP2 gain-of-function → ↑RAS–MAPK**;
LS/NSML variants : **catalytically impaired (dominant-negative) SHP2 → PI3K–AKT/mTOR-shifted signaling**

Regular diet



Impaired adipocyte differentiation

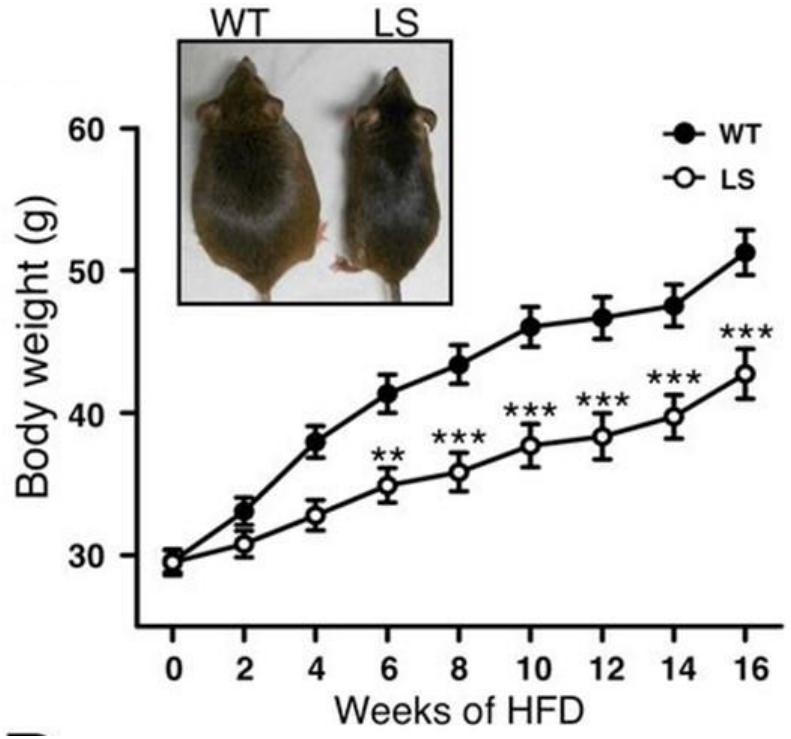




Tajan *et al.* PNAS **2014**; PMID: 25288766

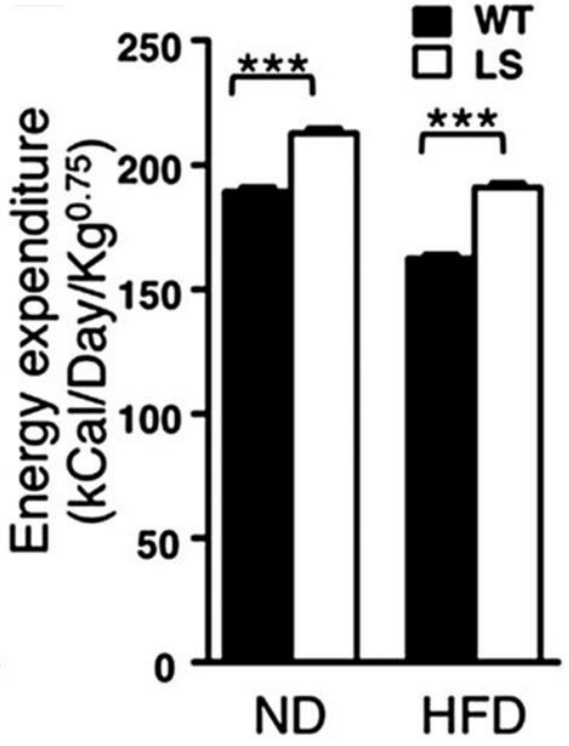
Animal model with SHP-2 (*PTPN11*) mutation

High fat diet



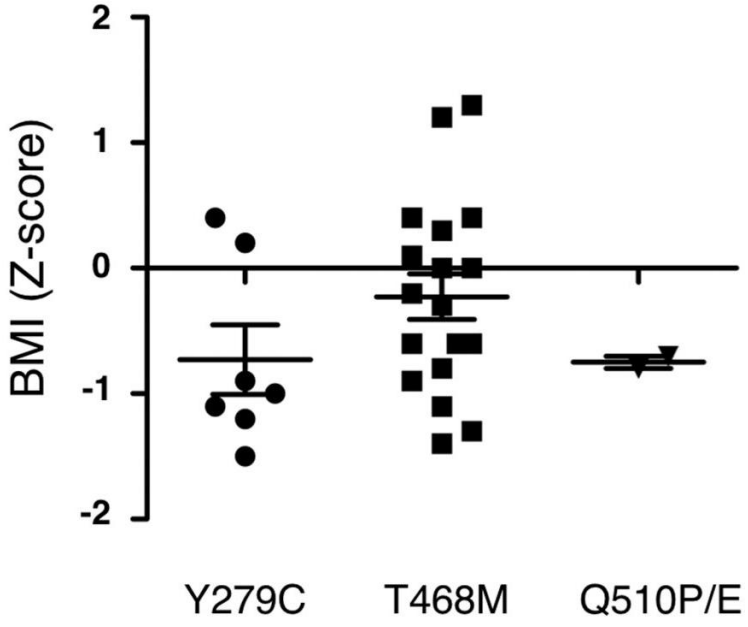
LS Mice Are Resistant to HFD-Induced Obesity

Caloric expenditure



28 adults with NSML

Z-score of adipose tissue between -2.4 to -1.8



Tajan *et al.* PNAS **2014**; PMID: 25288766

Unfavorable metabolic profile in Noonan syndrome

185 patients (112 prepubertal children and 73 adults)

NS (n = 178) and CFCS (n = 7)

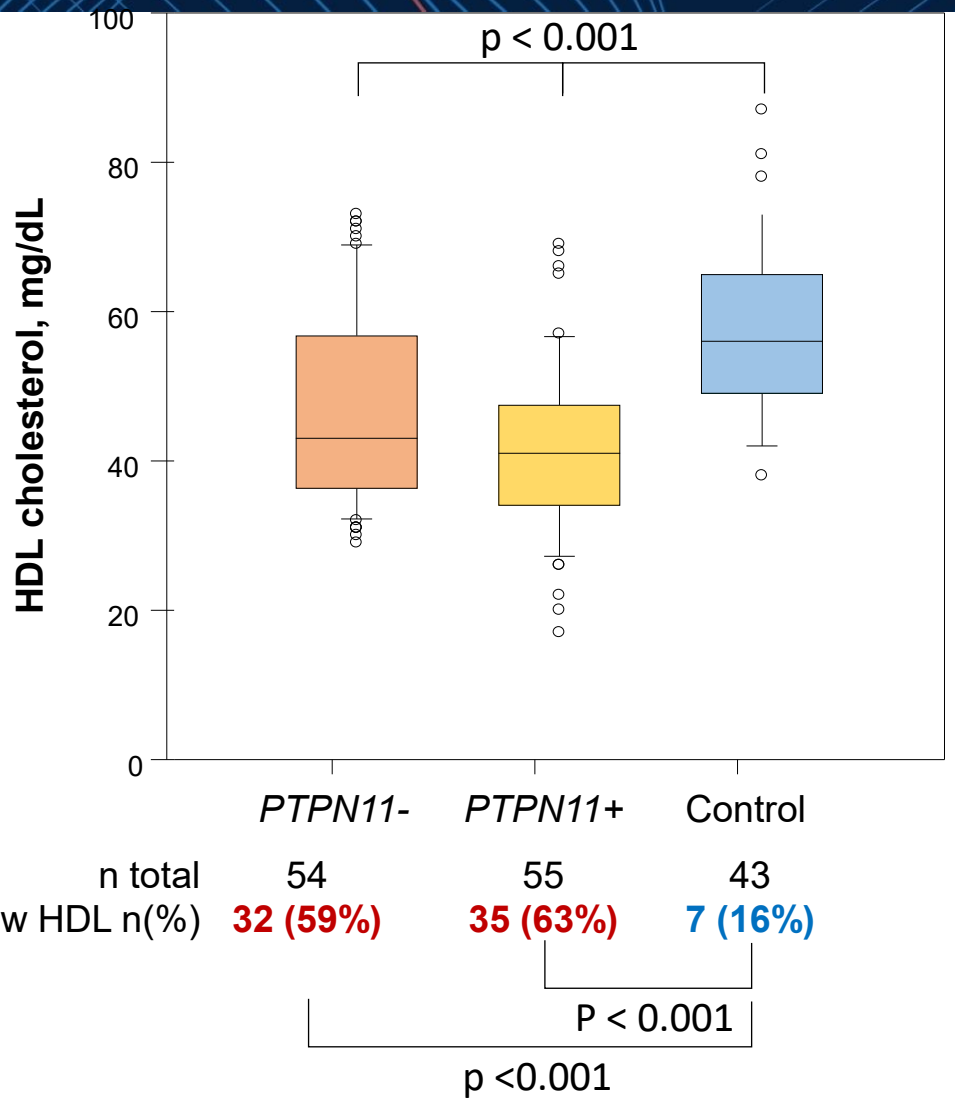
Exclusion criteria: Medications that interfere with glucose or lipid homeostasis, chronic disease malnutrition, and a positive familial history of dyslipidemia and diabetes mellitus.

Control group (n = 43) : healthy children from the same community as the patients.

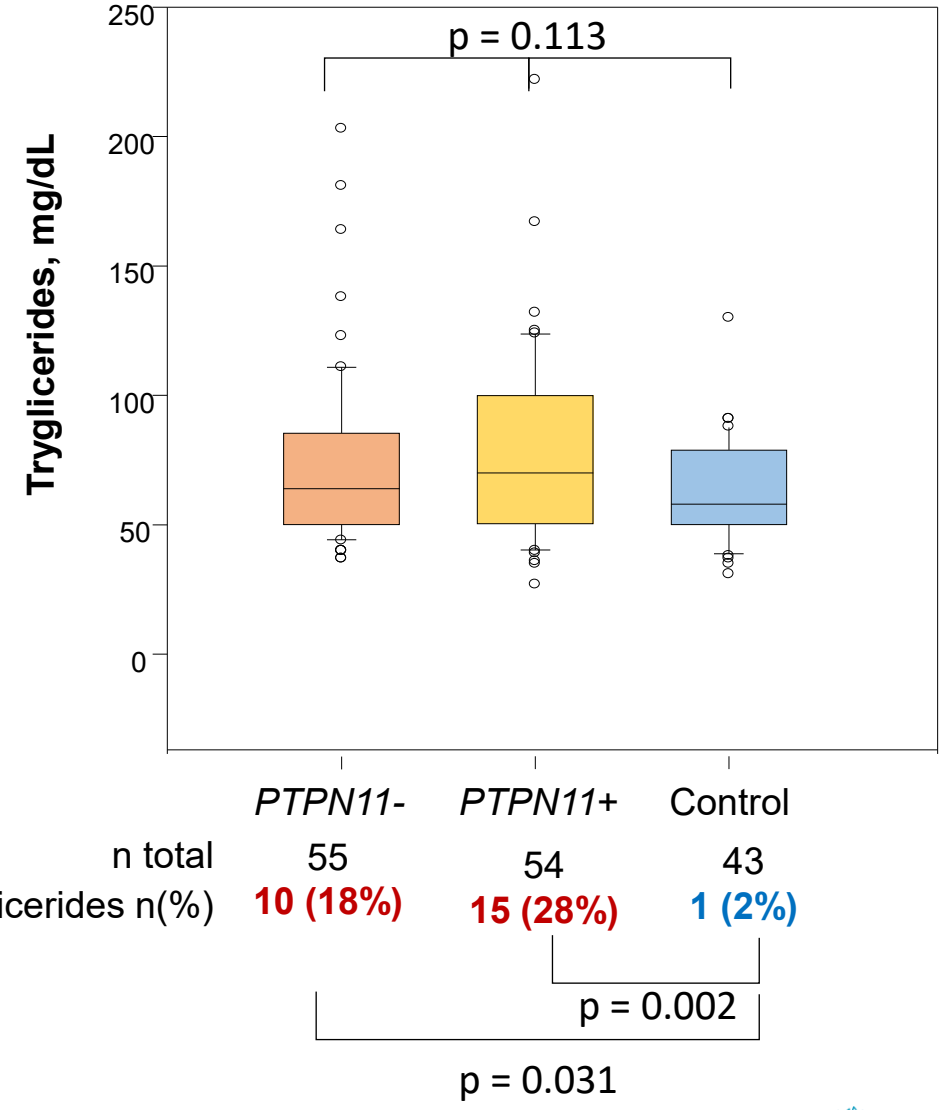
	NS (Total) n:112	NS (PTPN11 +) n:57	NS (PTPN11 -) n:55	Controls n:43	p (NS vs control)	p (PTPN11 + vs -)
Sex (F:M)	46:66	19:38	27:28	19:24	0.865	0.133
CA, years	7.7 (2.6 to 16)	7.1 (4.1 to 16)[a]	8.4 (2.6 to 14.4)[a]	9.7 (7.2 to 12.6)	<0.001	0.221
Height SDS	-2.2 ± 1.2	-2.3 ± 1.1 [a]	- 2.1 ± 1.3[a]	0.9 (-1.7 to 2.1)	<0.001	0.459
BMI SDS	-0.4 (-4.7 to 2.4)	-0.5 (-3.2 to 1.3)	- 0.3 (-4.7 to 2.4)	-0.4 (-2.0 to 1.7)	0.293	0.777

Noronha et al. Am J Med Genet A. **2021** PMID: **33382187**

Low HDL-cholesterol



Elevated triglycerides levels

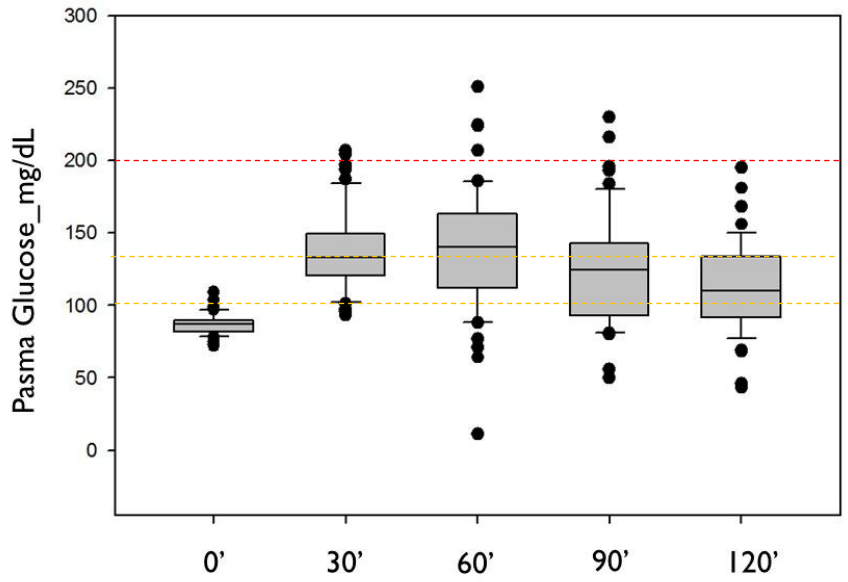


Noronha et al. Am J Med Genet A. **2021** PMID: **33382187**

Frequency of Glucose Intolerance in Noonan Syndromes

54 patients with NS
(31 females / 22 males)
CA = 14.5 to 61.2 years.

75g OGTT



Ten patients (18%) had impaired glucose tolerance (IGT)

Abnormal OGTT

5 males and 5 females

***PTPN11* (6x)**,
RIT1, *LZTR1*, *RAF1*, *SHOC2*

Age: 26.5 ± 5.6 y (17.8 to 37.7 y)

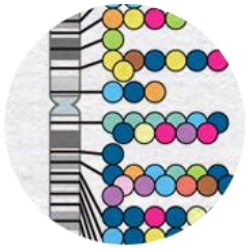
BMI: 21 ± 3 kg/m^2

- 2 underweight
- 7 appropriate weight
- 1 overweight

Low HDL-cholesterol 50%

Noronha et al. Am J Med Genet A. **2021** PMID: **33382187**

Association studies



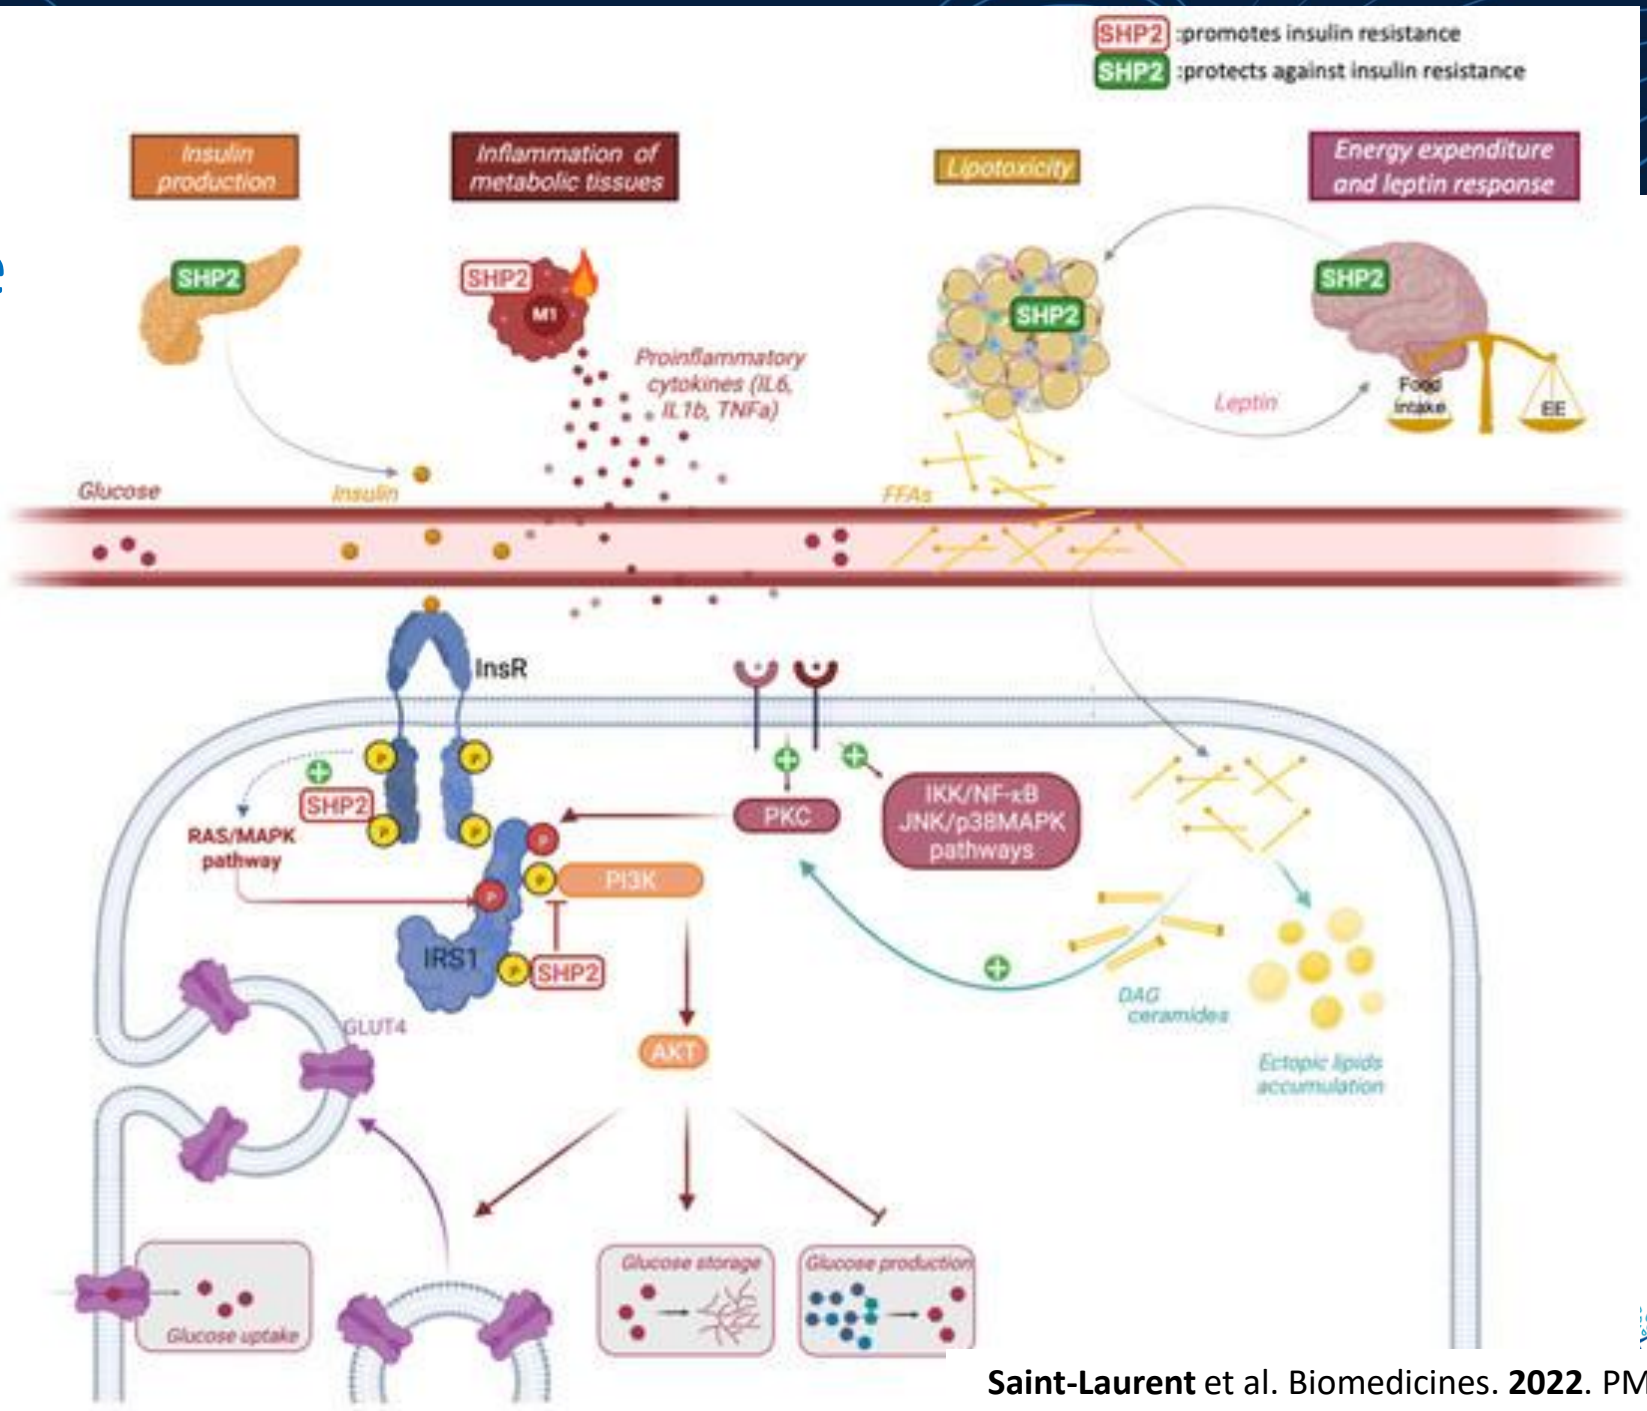
GWAS Catalog

SNPs in *PTPN11* associated with:

- Low LDL-cholesterol levels (5 associations)
- Low HDL-cholesterol levels (4 associations)
- Triglycerides (2 associations)

Diagnosis of Metabolic Syndrome	
Adult Criteria 3+ criteria	**Pediatric Criteria 2+ criteria**
WC > 102 cm (men) or 88 cm (women)	WC ≥ 90th percentile for age and gender
Triglycerides ≥ 150 mg/dL	Triglycerides ≥ 150 mg/dL
HDL-C < 40 (men) or < 50 (women)	HDL-C < 40 mg/dL
Systolic BP > 130 mmHg or > 85 mmHg diastolic	Systolic BP ≥ 130 or diastolic ≥ 85 mmHg
Fasting glucose ≥ 100 mg/dL Or known T2DM	Fasting glucose ≥ 100 mg/dL Or known T2DM

SHP-2 (*PTPN11*) and Insulin Resistance



Saint-Laurent et al. Biomedicines. **2022**. PMID: **36140242**

Lipid profile in Noonan syndrome: Italian cohort

N = 93
CA = 9.5 ± 6.2 years
BMI SDS = -0.3 ± 1.2
52.7% *PTPN11*

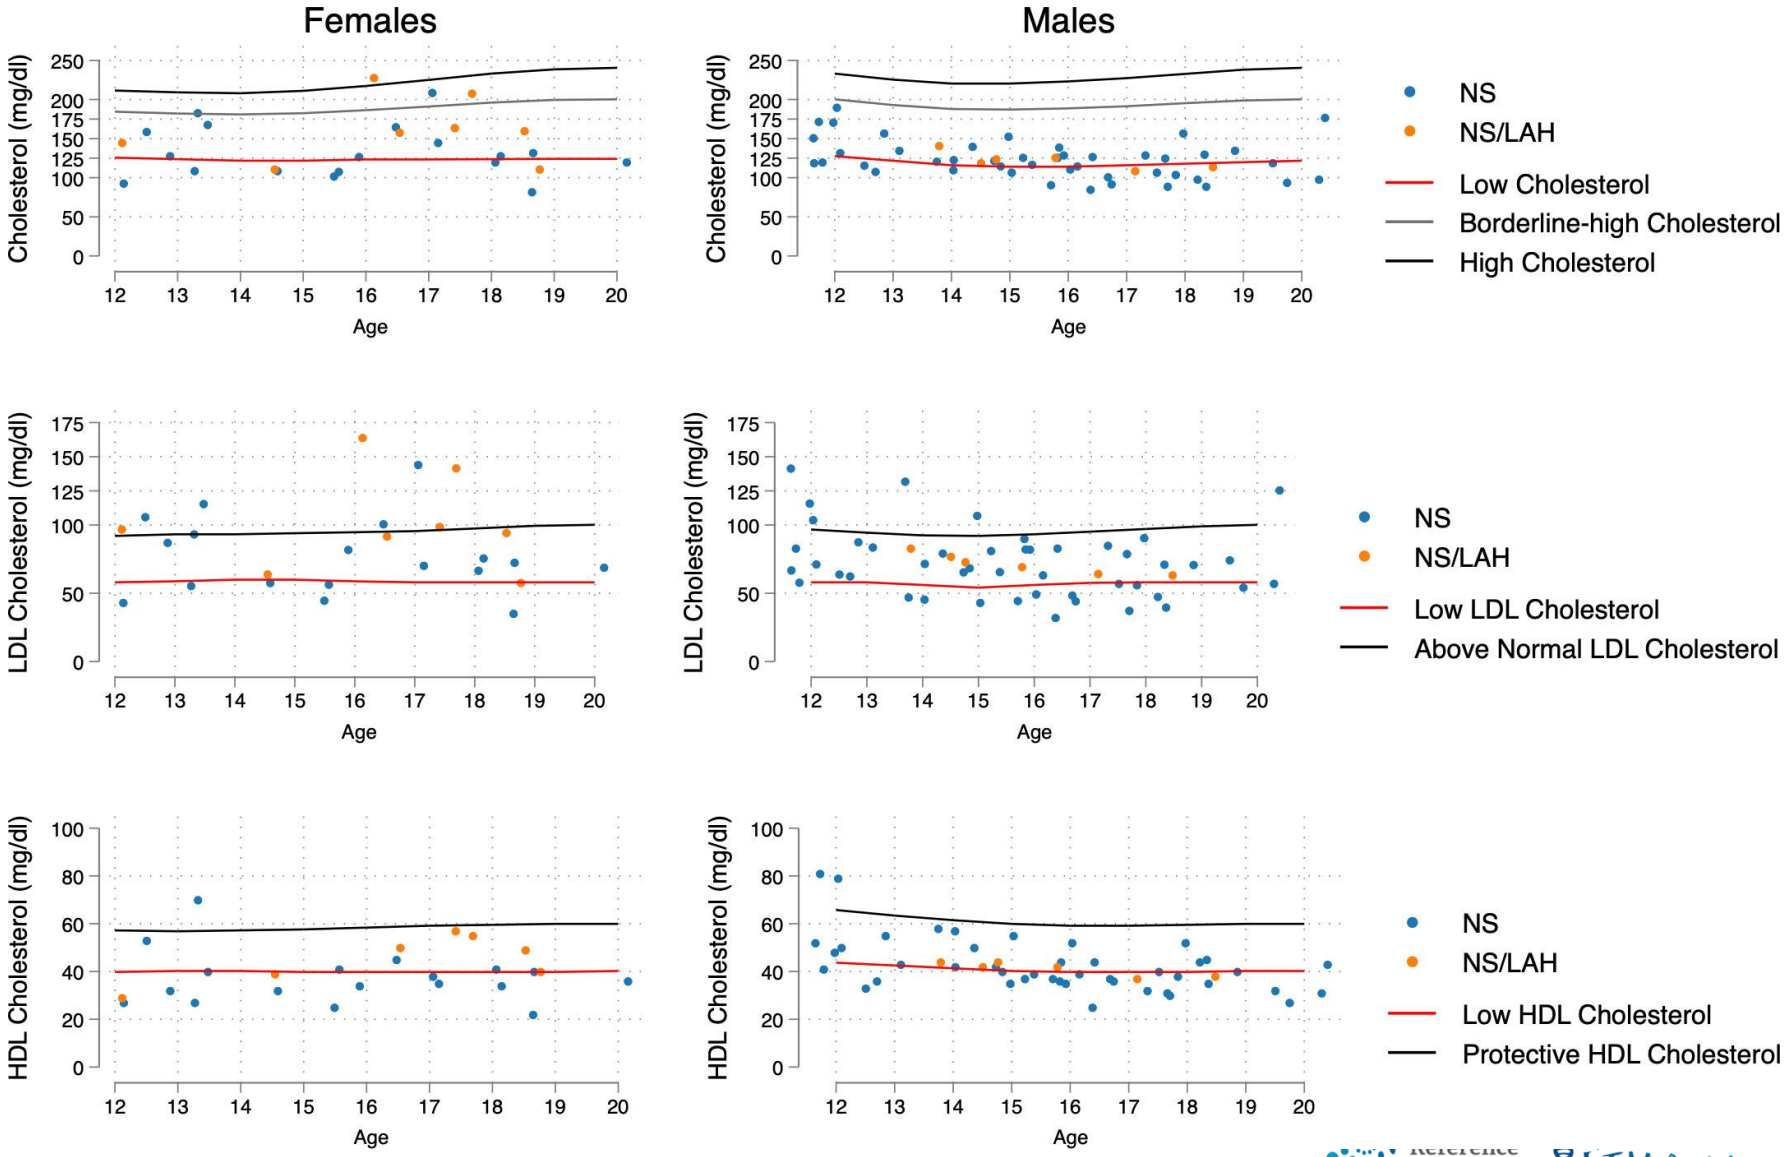
Low

- Total cholesterol
- HDL-cholesterol

(in particular in *PTPN11*)

Triglycerides showed an increasing trend with age only in NS females.

Normal glucose metabolism (HOMA-IR)



Tamburrino et al. Front Endocrinol (Lausanne). **2023** PMID: **37588986**

Take home message

Patients with NS, especially those with *PTPN11*, exhibit resistance to weight gain

- Low BMI is frequently observed in childhood, but in adulthood it is a phenotype more commonly seen in men with Noonan syndrome.

There appears to be a metabolic profile in patients with Noonan syndrome characterized by:

- Resistance to weight gain
- Low total cholesterol and HDL cholesterol
- Tendency toward elevated triglycerides

European Reference Networks ITHACA

Take home message

In our clinic, we currently have 81 adult patients with NS under annual follow-up

- None have developed diabetes or had a cardiovascular event.

(70% women, median age 31 years)

Long-term, large cohort studies are needed to define the clinical significance of these findings in terms of:

- Cardiovascular risk
- Risk for diabetes
